Universality in Complex Wishart ensembles: The 1 cut case

M. Y. Mo

Abstract

We considered $N \times N$ Wishart ensembles in the class $W_{\mathbb{C}}(\Sigma_N, M)$ (complex Wishart matrices with M degrees of freedom and covariance matrix Σ_N) such that N_0 eigenvalues of Σ_N is 1 and $N_1 = N - N_0$ of them are a. We studied the limit as M, N, N_0 and N_1 all go to infinity such that $\frac{N}{M} \to c$, $\frac{N_1}{N} \to \beta$ and $0 < c, \beta < 1$. In this case, the limiting eigenvalue density can either be supported on 1 or 2 disjoint intervals in $\mathbb{R}_+$. In the previous paper [28], we studied the universality in the case when the limiting eigenvalue density is supported on 2 intervals and in this paper, we continue the analysis and study the case when the support consists of a single interval. By using Riemann-Hilbert analysis, we have shown that under proper rescaling of the eigenvalues, the limiting correlation kernel is given by the sine kernel and the Airy kernel in the bulk and the edge of the spectrum respectively. As a consequence, the behavior of the largest eigenvalue in this model is described by the Tracy-Widom distribution.

1 Introduction

Let X be an $M \times N$ (assuming $M \geq N$) matrix with i.i.d. complex Gaussian entries whose real and imaginary parts have variance $\frac{1}{2}$ and zero mean. Let Σ_N be an $N \times N$ positive definite Hermitian matrix with eigenvalues $a_1, \ldots, a_N$ (not necessarily distinct). In this paper, we will consider the case where Σ_N has only 2 distinct eigenvalues, 1 and a such that N_1 of its eigenvalues are a and $N - N_1$ of them are 1. We will assume that $\frac{N}{M} \to c$ and $\frac{N_1}{N} \to \beta$ as $N, M \to \infty$ and that $0 < c, \beta < 1$. To be precise, we will assume the following

$$cM - N = \tau_1 = O(1), \quad N\beta - N_1 = \tau_2 = O(1), \quad M, N, N_1 \to \infty. \tag{1.1}$$

Let $\Sigma_N^{\frac{1}{2}}$ be any Hermitian square root of Σ_N. Then the columns of the matrix $X\Sigma_N^{\frac{1}{2}}$ are random vectors with variances $\frac{1}{2}\sqrt{a_j}$. Let the matrix B_N be the following

$$B_N = \frac{1}{M}\Sigma_N^{\frac{1}{2}} X^{\dagger} X \Sigma_N^{\frac{1}{2}}, \tag{1.2}$$

Then B_N is the sample covariance matrix of the columns of $X\Sigma_N^{\frac{1}{2}}$, while Σ_N is the covariance matrix. In particular, B_N is a complex Wishart matrix in the class $W_{\mathbb{C}}(\Sigma_N, M)$.

The sample covariance matrix is a fundamental tool in the studies of multivariate statistics and its distribution is already known to Wishart at around 1928 (See e.g. [29])

$$\mathcal{P}(B_N) = \frac{1}{C} e^{-M\mathrm{tr}(\Sigma^{-1}B_N)} \left(\det S\right)^{M-N}, \quad M \geq N, \tag{1.3}$$

for some normalization constant C.

Let $y_1, \ldots, y_N > 0$ be the eigenvalues of the sample covariance matrix B_N. Then in the case where N_1 eigenvalues of Σ_N is a and $N - N_1$ is 1, the joint probability density function (j.p.d.f) for the eigenvalues of B_N is given by

$$\mathcal{P}(y) = \frac{1}{Z_{M,N}} \prod_{i<j}(y_i - y_j) \prod_{j=1}^{N} y_j^{M-N} \det\left[y_k^{d_j^N - 1} e^{-Ma_j^{-1}y_k}\right]_{1 \leq j,k, \leq N}, \tag{1.4}$$

where $Z_{M,N}$ is a normalization constant and d_j^N, a_j are given by

$$\begin{aligned} &d_j^N = j, \quad a_j = 1, \quad 1 \leq j \leq N - N_1, \\ &d_j^N = j - N + N_1, \quad a_j = a, \quad N - N_1 < j \leq N. \end{aligned}$$

In this paper we will study the asymptotic limit of the Wishart distribution with $\frac{N}{M} \to c$ and $\frac{N_1}{N} \to \beta$ as M, $N \to \infty$ in such a way that $0 < \beta, c < 1$. In this case, the empirical distribution function (e.d.f) F_N of the eigenvalues will converge weakly to a nonrandom p.d.f. F, which will be supported on either 1 or 2 intervals in $\mathbb{R}_+$. By applying the results of [15] to our case, we can extract properties of the measure F from the solutions of an algebraic equation (See Section 3 for details)

$$\begin{aligned} &za\xi^3 + (A_2 z + B_2)\xi^2 + (z + B_1)\xi + 1 = 0, \\ &A_2 = (1 + a), \quad B_2 = a(1 - c), \\ &B_1 = 1 - c(1 - \beta) + a(1 - c\beta). \end{aligned} \tag{1.5}$$

The results in [15] imply that the real zeros of the function $\frac{dz(\xi)}{d\xi}$ determines the boundary points of the support of F. Since the zeros of $\frac{dz(\xi)}{d\xi}$ coincide with the zeros of the following quartic polynomial,

$$\begin{aligned} &a^2(1 - c)\xi^4 + 2(a^2(1 - c\beta) + a(1 - c(1 - \beta))\xi^3 \\ &\qquad + (1 - c(1 - \beta) + a^2(1 - c\beta) + 4a)\xi^2 + 2(1 + a)\xi + 1 = 0, \end{aligned} \tag{1.6}$$

the real roots of (1.6) are important in the determination of Supp(F). In particular, we have the following result. (See Theorem 5)

Theorem 1. *Let Δ be the discriminant of the quartic polynomial (1.6). If $\Delta < 0$, then the support of F consists of a single intervals.*

In our previous paper [28], we have shown that $\text{Supp}(F)$ consists of 2 disjoint intervals if and only if $\Delta > 0$ and have obtained the asymptotic eigenvalue statistics in that case. In this paper, we consider the case when $\Delta < 0$ and together with [28], we have proven the universality in this class of complex Wishart ensemble for all $\Delta \neq 0$. When $\Delta = 0$, a phase transition takes place and the support of the eigenvalues splits into 2 disjoint intervals.

When $\Delta < 0$, we also have the following expression for the density function of F (See Theorem 6).

Theorem 2. *Let Δ be the discriminant of the quartic polynomial (1.6). Suppose $\Delta < 0$ and let $\gamma_1 < \gamma_2$ be the 2 real roots to (1.6) and γ_3, γ_4 be the 2 complex roots. Let λ_k, $k = 1, \ldots, 4$ be the following*

$$\lambda_k = -\frac{1}{\gamma_k} + c\frac{1-\beta}{1+\gamma_k} + c\frac{a\beta}{1+a\gamma_k}, \quad k = 1, \ldots, 4.$$

Then all the λ_k are distinct and the p.d.f F is supported on $[\lambda_1, \lambda_2]$ with the following density $dF(z) = \rho(z)dz$

$$\rho(z) = \frac{3}{2\pi}\left|\left(\frac{r(z) + \sqrt{-\frac{1}{27a^4z^4}D_3(z)}}{2}\right)^{\frac{1}{3}} - \left(\frac{r(z) - \sqrt{-\frac{1}{27a^4z^4}D_3(z)}}{2}\right)^{\frac{1}{3}}\right|, \tag{1.7}$$

where $D_3(z)$ and $r(z)$ are given by

$$D_3(z) = (1-a)^2\prod_{j=1}^{4}(z - \lambda_j),$$

$$r(z) = \frac{1}{27}\Bigg(-\frac{2B_2^3}{a^3}z^{-3} + \left(\frac{9B_1B_2}{a^2} - \frac{6A_2B_2^2}{a^3}\right)z^{-2} + \left(\frac{9B_2}{a^2} + \frac{9B_1A_2}{a^2} - \frac{27}{a} - \frac{6A_2^2B_2}{a^3}\right)z^{-1} + \left(\frac{9A_2}{a^2} - \frac{2A_2^3}{a^3}\right)\Bigg).$$

The constants A_1, B_1 and B_2 in the above equation are defined by

$$A_2 = (1+a), \quad B_2 = a(1-c), \quad B_1 = 1 - c(1-\beta) + a(1-c\beta).$$

The cube root in (3.23) is chosen such that $\sqrt[3]{A} \in \mathbb{R}$ for $A \in \mathbb{R}$ and the square root is chosen such that $\sqrt{A} > 0$ for $A > 0$.

Remark 1. *Since $D_3(z)$ can be written as*

$$\frac{D_3(z)}{a^4z^4} = -27\left(r(z)\right)^2 - 4\left(p(z)\right)^3, \tag{1.8}$$

for some polynomial $p(z)$ *in* z^{-1}*. We see that if* $r(z)$ *vanishes at any of the* λ_k*, then* $D_3(z)$ *will have at least a double root at these points, hence* $r(\lambda_k) \neq 0$*. From this and (1.7), we see that the density* $\rho(z)$ *vanishes like a square root at the points* λ_k*,* $k = 1, 2$*.*

$$\rho(z) = \frac{\rho_k}{\pi}|z - \lambda_k|^{\frac{1}{2}} + O\left((z - \lambda_k)\right), \quad z \to \lambda_k. \tag{1.9}$$

An open problem in the studies of Wishart ensembles is the universality and the distribution of the largest eigenvalue. Although the Wishart distribution is known for a long time, results in the universality and the largest eigenvalue distribution were only obtained recently and only for spiked models [24] whose covariance matrices are finite perturbations of the identity matrix [6], [7], [8], [16], [21], [22], [24], [25], [32], [33]. The result in this paper is one of the few results obtained for models with covariance matrices that is not a finite perturbation of the identity matrix. (See also [20], in which the largest eigenvalue distribution was also derived for ensembles whose covariance matrix is not a finite perturbation of the identity matrix. However, in [20], the parameters $c = \frac{N}{M}$, $\beta = \frac{N_1}{N}$ and the eigenvalues of the covariance matrix have to satisfy a condition which is not true in our case.)

In this paper, we use an important result by Baik, Ben-Arous and Péché [7] which shows that the correlation functions of the eigenvalues can be expressed in terms of a Fredholm determinant with kernel $K_{M,N}(x, y)$. In [14] and [16], the authors have expressed this kernel in terms of multiple orthogonal polynomials (See Section 2 for details) and have shown that the m-point correlation function for the Wishart distribution (1.3) is given by

$$\mathcal{R}_m^{(M,N)}(y_1, \ldots, y_m) = \det\left(K_{M,N}(y_j, y_k)\right)_{1 \leq j,k \leq m} \tag{1.10}$$

where $\mathcal{R}_m^{(M,N)}(y_1, \ldots, y_m)$ is the m-point correlation function

$$\mathcal{R}_m^{(M,N)}(y_1, \ldots, y_m) = \frac{N!}{(N-m)!} \int_{\mathbb{R}_+} \cdots \int_{\mathbb{R}_+} \mathcal{P}(y) dy_{m+1} \ldots dy_N. \tag{1.11}$$

By computing the asymptotics of the correlation kernel in (1.10) through the asymptotics of multiple Laguerre polynomials, we have proven the universality of the correlation function when M, N and $N_1 \to \infty$.

Theorem 3. *Suppose* Δ *in Theorem 1 is negative. Let* $\rho(z)$ *be the density function of* F *in Theorem 2. Then for any* $x_0 \in (\lambda_1, \lambda_2)$ *and* $m \in \mathbb{N}$*, we have*

$$\begin{aligned} \lim_{N,M \to \infty} \left(\frac{1}{M\rho(x_0)}\right)^m \mathcal{R}_m^{(M,N)}\left(x_0 + \frac{u_1}{M\rho(x_0)}, \ldots, x_0 + \frac{u_m}{M\rho(x_0)}\right) \\ = \det\left(\frac{\sin \pi(u_i - u_j)}{\pi(u_i - u_j)}\right)_{i,j=1}^m. \end{aligned} \tag{1.12}$$

uniformly for any $(u_1, \ldots, u_m)$ *in compact subsets of* $\mathbb{R}^m$*.*

On the other hand, let $x_0 = \lambda_k$, $k = 1, 2$, *then for any* $m \in \mathbb{N}$, *we have*

$$\begin{aligned}\lim_{N,M\to\infty}\left(\frac{1}{(M\rho_k)^{\frac{2}{3}}}\right)^m \mathcal{R}_m^{(M,N)}\left(\lambda_k + (-1)^k\frac{u_1}{(M\rho_k)^{\frac{2}{3}}}, \ldots, \lambda_k + (-1)^k\frac{u_m}{(M\rho_k)^{\frac{2}{3}}}\right)\\ = \det\left(\frac{\mathrm{Ai}(u_i)\mathrm{Ai}'(u_j) - \mathrm{Ai}'(u_i)\mathrm{Ai}(u_j)}{u_i - u_j}\right)_{i,j=1}^m,\end{aligned} \tag{1.13}$$

uniformly for any $(u_1, \ldots, u_m)$ *in compact subsets of* $\mathbb{R}^m$, *where* $\mathrm{Ai}(z)$ *is the Airy function and* ρ_k, $k = 1, 2$ *are the constants in (1.9).*

Recall that the Airy function is the unique solution to the differential equation $v'' = zv$ that has the following asymptotic behavior as $z \to \infty$ in the sector $-\pi + \epsilon \le \arg(z) \le \pi - \epsilon$, for any $\epsilon > 0$.

$$\mathrm{Ai}(z) = \frac{1}{2\sqrt{\pi}z^{\frac{1}{4}}}e^{-\frac{2}{3}z^{\frac{3}{2}}}\left(1 + O(z^{-\frac{3}{2}})\right), \quad -\pi + \epsilon \le \arg(z) \le \pi - \epsilon, \quad z \to \infty. \tag{1.14}$$

where the branch cut of $z^{\frac{3}{2}}$ in the above is chosen to be the negative real axis.

Since the limiting kernel takes the form of the Airy kernel (1.13), by a well-known result of Tracy and Widom [31], we have the following

Theorem 4. *Let* y_1 *be the largest eigenvalue of* B_N, *then we have*

$$\lim_{M,N\to\infty}\mathbb{P}\left((y_1 - \lambda_2)(M\rho_2)^{\frac{2}{3}} < s\right) = TW(s), \tag{1.15}$$

where $TW(s)$ *is the Tracy-Widom distribution*

$$TW(s) = \exp\left(-\int_s^\infty (t - s)q^2(t)dt\right), \tag{1.16}$$

and $q(s)$ *is the solution of Painlevé II equation*

$$q''(s) = sq(s) + 2q^3(s),$$

with the following asymptotic behavior as $s \to \infty$.

$$q(s) \sim -\mathrm{Ai}(s), \quad s \to +\infty.$$

The results obtained in this paper are obtained through the Riemann-Hilbert analysis. As in [12] and [26], a Riemann surface of the form (1.5), together with the zero set of a real function $h(x)$ related to this Riemann surface are essential to the implementation of the Riemann-Hilbert analysis. This function $h(x)$ is given as follows. If we express the

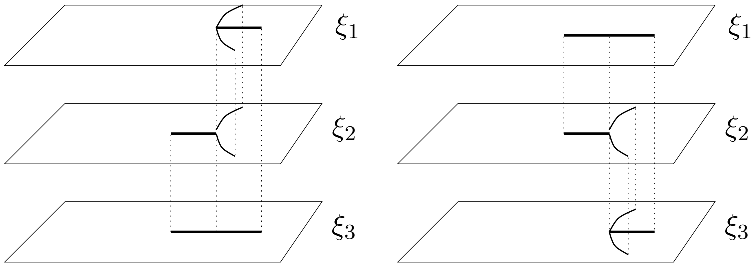

Figure 1: Possible sheet structures of the Riemann surface. For the implementation of the Riemann-Hilbert analysis, we need to show that the Riemann surface has the sheet structure shown on the right hand side.

solutions ξ in (1.5) as analytic functions of z, then the three solutions to (1.5) behave as follows when $z \to \infty$.

$$\begin{aligned} \xi_1(z) &= -\frac{1}{z} + O(z^{-2}), \quad z \to \infty, \\ \xi_2(z) &= -1 + \frac{c(1-\beta)}{z} + O(z^{-2}), \quad z \to \infty, \\ \xi_3(z) &= -\frac{1}{a} + \frac{c\beta}{z} + O(z^{-2}), \quad z \to \infty. \end{aligned} \tag{1.17}$$

Then the function $h(x)$ is defined by

$$h(x) = \operatorname{Re}\left(\int_{\lambda_3}^{x} \xi_2(z) - \xi_3(z)dz\right) \tag{1.18}$$

In order to implement the Riemann-Hilbert analysis, we must determine the sheet structure of the Riemann surface (1.5) and the topology of the zero set $\mathfrak{H}$ of $h(x)$. Since our model depends on three parameters c, a and β, while the models in [12] and [26] depend only on one parameter a, the determination of both the sheet structure of the Riemann surface and the topology of $\mathfrak{H}$ are considerably more difficult in our case and a large part of this paper is devoted to resolve these difficulties so that Riemann-Hilbert analysis like those in [12] and [26] can be applied.

To determine the sheet structure of (1.5), note that although we assume the discriminant Δ in Theorem 1 is negative, which means that the Riemann surface (1.5) has 2 real and 2 complex branch points, it is unclear which Riemann sheet do these branch points belong to and these different situations will result in different sheet structures of the Riemann surface as indicated in Figure 1. In order to determine the sheet structure of the Riemann surface, we need to analyze the analyticity of the solutions ξ_j in the vicinity of the points λ_k in Theorem 2. This requires the type of analysis used in [27], which is very difficult to carry out in our case. As in [28], we overcome these difficulties by showing that the Stieltjes transform of the limiting eigenvalue distribution satisfies (1.5). Then by using properties of the Stieltjes transform obtained in [3], [4], [5], [15], [30], we were able to determine the sheet structure of the Riemann surface (1.5).

The determination of the topology of the set $\mathfrak{H}$ in this case is also much more complicated and a thorough analysis of this set making use of properties of harmonic functions is carried out in Section 3.2.1.

For theoretical reasons, the model studied in this paper is crucial in understanding of the phase transition behavior that occurs in Wishart ensembles. (See [7]). When the 2 intervals in the support of F closes up, a phase transition takes place and the correlation kernel will demonstrate a different behavior at the point where the support closes up. With the Riemann-Hilbert technique used in this paper, such behavior can be studied rigorously as in [13] and the eigenvalue correlation function near the critical point will be given by the Pearcey kernel. For practical reasons, many covariance matrices appearing in fields of science are not finite perturbations of the identity matrix. In fact, covariance matrices that have groups of distinct eigenvalues are accepted models in various areas such as the correlation of genes in microarray analysis and the correlation of the returns of stocks in finance.

2 Multiple Laguerre polynomials and the correlation kernel

The main tool in our analysis involves the use of multiple orthogonal polynomials and the Riemann-Hilbert problem associated with them. In this section we shall recall the results in [14] and [16] and express the correlation kernel $K_{M,N}(x,y)$ in (1.10) in terms of multiple Laguerre polynomials. In Section 4, we will apply Riemann-Hilbert analysis to obtain the asymptotics of these multiple Laguerre polynomials and use them to prove Theorem 3.

We shall not define the multiple Laguerre polynomials in the most general setting, but only define the ones that are relevant to our set up. Readers who are interested in the theory of multiple orthogonal polynomials can consult the papers [1], [2], [14], [23]. Let $L_{n_1,n_2}(x)$ be the monic polynomial such that

$$\begin{aligned}
&\int_0^\infty L_{n_1,n_2}(x)x^{i+M-N}e^{-Mx}dx = 0, \quad i = 0,\ldots,n_1-1,\\
&\int_0^\infty L_{n_1,n_2}(x)x^{i+M-N}e^{-Ma^{-1}x}dx = 0, \quad i = 0,\ldots,n_2-1.
\end{aligned} \tag{2.1}$$

and let $Q_{n_1,n_2}(x)$ be a function of the form

$$Q_{n_1,n_2}(x) = A^1_{n_1,n_2}(x)e^{-Mx} + A^a_{n_1,n_2}(x)e^{-Ma^{-1}x}, \tag{2.2}$$

where $A^1_{n_1,n_2}(x)$ and $A^a_{n_1,n_2}(x)$ are polynomials of degrees $n_1 - 1$ and $n_2 - 1$ respectively, and that $Q_{n_1,n_2}(x)$ satisfies the following

$$\int_0^\infty x^i Q_{n_1,n_2}(x) x^{M-N} dx = \begin{cases} 0, & i = 0, \dots, n_1 + n_2 - 2; \\ 1, & i = n_1 + n_2 - 1. \end{cases} \tag{2.3}$$

The polynomial $L_{n_1,n_2}(x)$ is called the multiple Laguerre polynomial of type II and the polynomials $A^1_{n_1,n_2}(x)$ and $A^a_{n_1,n_2}(x)$ are called multiple Laguerre polynomials of type I (with respect to the weights $x^{M-N}e^{-Mx}$ and $x^{M-N}e^{-Ma^{-1}x}$) [1], [2]. These polynomials exist and are unique. Moreover, they admit integral expressions [14].

Let us define the constants $h^{(1)}_{n_1,n_2}$ and $h^{(2)}_{n_1,n_2}$ to be

$$\begin{aligned} h^{(1)}_{n_1,n_2} &= \int_0^\infty L_{n_1,n_2}(x) x^{n_1+M-N} e^{-Mx} dx, \\ h^{(2)}_{n_1,n_2} &= \int_0^\infty L_{n_1,n_2}(x) x^{n_2+M-N} e^{-Ma^{-1}x} dx. \end{aligned} \tag{2.4}$$

Then the following result in [14] and [16] allows us to express the correlation kernel in (1.10) in terms of a finite sum of the multiple Laguerre polynomials.

Proposition 1. *The correlation kernel in $K_{M,N}(x,y)$ (1.10) can be expressed in terms of multiple Laguerre polynomials as follows*

$$\begin{aligned} (xy)^{\frac{N-M}{2}}(x-y)K_{M,N}(x,y) = {} & L_{N_0,N_1}(x)Q_{N_0,N_1}(x) \\ & - \frac{h^{(1)}_{N_0,N_1}}{h^{(1)}_{N_0-1,N_1}} L_{N_0-1,N_1}(x)Q_{N_0+1,N_1}(x) \\ & - \frac{h^{(2)}_{N_0,N_1}}{h^{(2)}_{N_0,N_1-1}} L_{N_0,N_1-1}(x)Q_{N_0,N_1+1}(x) \end{aligned} \tag{2.5}$$

where $N_0 = N - N_1$.

This result allows us to compute the limiting kernel once we obtain the asymptotics for the multiple Laguerre polynomials.

3 Stieltjes transform of the eigenvalue distribution

In order to study the asymptotics of the correlation kernel, we would need to know the asymptotic eigenvalue distribution of the Wishart ensemble (1.3). Let $F_N(x)$ be the empirical distribution function (e.d.f) of the eigenvalues of B_N (1.2). The asymptotic properties of $F_N(x)$ can be found by studying its Stieltjes transform.

The Stieltjes transform of a probability distribution function (p.d.f) $G(x)$ is defined by

$$m_G(z) = \int_{-\infty}^\infty \frac{1}{\lambda - z} dG(x), \quad z \in \mathbb{C}^+ = \{z \in \mathbb{C} : \operatorname{Im}(z) > 0\}. \tag{3.1}$$

Given the Stieljes transform, the p.d.f can be found by the inversion formula

$$G([a,b]) = \frac{1}{\pi} \lim_{\epsilon \to 0^+} \int_a^b \mathrm{Im}\left(m_G(s+i\epsilon)\right) ds. \tag{3.2}$$

The properties of the Stieltjes transform of $F_N(x)$ has been studied by Bai, Silverstein and Choi in the papers [15], [3], [4], [5], [30]. We will now summarize the results that we need from these papers.

First let us denote the e.d.f of the eigenvalues of Σ_N by H_N, that is, we have

$$dH_N(x) = \frac{1}{N} \sum_{j=1}^{N} \delta_{a_j}.$$

Furthermore, we assume that as $N \to \infty$, the distribution H_N weakly converges to a distribution function H. Then as $N \to \infty$, the e.d.f $F_N(x)$ converges weakly to a nonrandom p.d.f F, and that the Stieltjes transform m_F of $F(x)$ satisfies the following equation [15], [30]

$$m_F(z) = \int_{\mathbb{R}} \frac{1}{t(1-c-czm_F) - z} dH(t). \tag{3.3}$$

Let us now consider the closely related matrix $\underline{B}_N$

$$\underline{B}_N = \frac{1}{N} X \Sigma_N X^{\dagger}. \tag{3.4}$$

The matrix $\underline{B}_N$ has the same eigenvalues as B_N together with an addition $M-N$ zero eigenvalues. Therefore the e.d.f $\underline{F}_N$ of the eigenvalues of $\underline{B}_N$ are related to F_N by

$$\underline{F}_N = (1-c_N) I_{[0,\infty)} + c_N F_N, \quad c_N = \frac{N}{M}. \tag{3.5}$$

where $I_{[0,\infty)}$ is the step function that is 0 on $\mathbb{R}_-$ and 1 on $\mathbb{R}_+$. In particular, as $N \to \infty$, the distribution $\underline{F}_N$ converges weakly to a p.d.f $\underline{F}$ that is related to F by

$$\underline{F} = (1-c) I_{[0,\infty)} + cF \tag{3.6}$$

and their Stieltjes transforms are related by

$$m_{\underline{F}}(z) = -\frac{1-c}{z} + c m_F(z). \tag{3.7}$$

Then from (3.3), we see that the Stieltjes transform $m_{\underline{F}}(z)$ satisfies the following equation

$$m_{\underline{F}}(z) = -\left(z - c \int_{\mathbb{R}} \frac{t dH(t)}{1 + t m_{\underline{F}}}\right)^{-1}. \tag{3.8}$$

This equation has an inverse [4], [5]

$$z(m_{\underline{F}}) = -\frac{1}{m_{\underline{F}}} + c\int_{\mathbb{R}} \frac{t}{1+tm_{\underline{F}}} dH(t). \tag{3.9}$$

The points where $\frac{dz(\xi)}{d\xi} = 0$ are of significant interest to us as they are potential end points of the support of $\underline{F}$, due to the following result by Choi and Silverstein.

Lemma 1. [15] *If $z \notin \operatorname{supp}(\underline{F})$, then $m = m_{\underline{F}}(z)$ satisfies the following.*

1. *$m \in \mathbb{R} \setminus \{0\}$;*
2. *$-\frac{1}{m} \notin \operatorname{supp}(H)$;*
3. *Let z be defined by (3.9), then $z'(m) > 0$, where the prime denotes the derivative with respect to $m_{\underline{F}}$ in (3.9).*

Conversely, if m satisfies 1-3, then $z = z(m) \notin \operatorname{supp}(\underline{F})$.

This lemma allows us to identify the complement of $\operatorname{supp}(\underline{F})$ by studying the real points m such that $z'(m) > 0$.

Remark 2. *As pointed out in [8], Lemma 1 applies to any distribution G whose Stieltjes transform $m_G(z)$ (3.1) satisfies an equation of the form*

$$z(m_G) = -\frac{1}{m_G} + c_G\int_{\mathbb{R}} \frac{t}{1+tm_G} dH_G(t).$$

for some constant c_G and distribution $H_G(t)$.

3.1 Riemann surface and the Stieltjes transform

We will now restrict ourselves to the case when the matrix Σ_N has 2 distinct eigenvalues only. Without lost of generality, we will assume that one of these values is 1 and the other one is $a > 0$. Let $0 < \beta < 1$, we will assume that as $N \to \infty$, N_1 of the eigenvalues take the value a and $N_0 = N - N_1$ of the eigenvalues are 1 and that $\frac{N_1}{N} \to \beta$. That is, as $N \to \infty$, the e.d.f $H_N(x)$ converges to the following

$$dH_N(x) \to dH(x) = (1-\beta)\delta_1 + \beta\delta_a. \tag{3.10}$$

By substituting this back into (3.9), we see that the Stieltjes transform $\xi(z) = m_{\underline{F}}(z)$ is a solution to the following algebraic equation

$$z = -\frac{1}{\xi} + c\frac{1-\beta}{1+\xi} + c\frac{a\beta}{1+a\xi}. \tag{3.11}$$

Rearranging the terms, we see that $\xi = m_{\underline{F}}$ solves the following

$$\begin{aligned} &za\xi^3 + (A_2 z + B_2)\xi^2 + (z + B_1)\xi + 1 = 0, \\ &A_2 = (1+a), \quad B_2 = a(1-c), \\ &B_1 = 1 - c(1-\beta) + a(1-c\beta). \end{aligned} \tag{3.12}$$

This defines a Riemann surface $\mathcal{L}$ as a 3-folded cover of the complex plane.

By solving the cubic equation (3.12) or by analyzing the asymptotic behavior of the equation as $z \to \infty$, we see that these solutions have the behavior given by (1.17) as $z \to \infty$. On the other hand, as $z \to 0$, the 3 branches of $\xi(z)$ behave as follows

$$\begin{aligned} &\xi_\alpha(z) = -\frac{1-c}{z} + O(1), \quad z \to 0, \\ &\xi_\beta(z) = R_1 + O(z), \quad z \to 0, \\ &\xi_\gamma(z) = R_2 + O(z), \quad z \to 0. \end{aligned} \tag{3.13}$$

where the order of the indices α, β and γ does not necessarily coincide with the ones in (1.17) (i.e. we do not necessarily have $\alpha = 1$, $\beta = 2$ and $\gamma = 3$). The constants R_1 and R_2 are the two roots of the quadratic equation

$$a(1-c)x^2 + (1 - c(1-\beta) + a(1-c\beta))x + 1 = 0. \tag{3.14}$$

The functions $\xi_j(z)$ will not be analytic at the branch points of $\mathcal{L}$ and they will be discontinuous across the branch cuts joining these branch points. Moreover, from (3.13), one of the functions $\xi_j(z)$ will have a simple pole at $z = 0$. Apart from these singularities, however, the functions $\xi_j(z)$ are analytic.

3.2 Sheet structure of the Riemann surface

As explained in the introduction, the determination of the sheet structure of the Riemann surface (1.5) involves difficult analysis of the behavior of the $\xi_j(z)$ at the points λ_k. In order to implement Riemann-Hilbert analysis to obtain the asymptotics of the kernel in (1.10), we must show that $\xi_1(z)$ is not analytic at the real branch points λ_k, $k = 1, 2$. This will be achieved by making use of the properties of the Stieltjes transform.

In this section we will study the sheet structure of the Riemann surface $\mathcal{L}$. As we shall see, the branch $\xi_1(z)$ turns out to be the Stieljes transform $m_{\underline{F}}(z)$ and its branch cut will be the support of $\underline{F}$.

By Lemma 1, the real points at which $\frac{dz}{d\xi} > 0$ characterize the end points of Supp($\underline{F}$). The determine the support, let us differentiate (3.11) to obtain an expression of $\frac{dz}{d\xi}$ in terms of ξ.

$$\begin{aligned} \frac{dz}{d\xi} = \frac{1}{\xi^2(1+\xi)^2(1+a\xi)^2} \Bigg(& a^2(1-c)\xi^4 + 2(a^2(1-c\beta) + a(1-c(1-\beta))\xi^3 \\ & + (1 - c(1-\beta) + a^2(1-c\beta) + 4a)\xi^2 + 2(1+a)\xi + 1 \Bigg). \end{aligned} \tag{3.15}$$

In particular, the values of ξ at $\frac{dz}{d\xi}=0$ correspond to the roots of the quartic equation

$$\begin{aligned}a^2(1-c)\xi^4+2(a^2(1-c\beta)+a(1-c(1-\beta))\xi^3\\ +(1-c(1-\beta)+a^2(1-c\beta)+4a)\xi^2+2(1+a)\xi+1=0\end{aligned}\tag{3.16}$$

Let Δ be the discriminant of this quartic polynomial, then when $\Delta<0$, the equation (3.16) has 2 distinct real roots $\gamma_1<\gamma_2$ and 2 complex roots γ_3 and $\gamma_4=\overline{\gamma}_3$. One can check that the coefficients of (3.16) are all positive and hence $\gamma_1<\gamma_2<0$.

Let λ_k be the corresponding points in the z-plane

$$\lambda_k=-\frac{1}{\gamma_k}+c\frac{1-\beta}{1+\gamma_k}+c\frac{a\beta}{1+a\gamma_k},\quad k=1,\ldots,4.\tag{3.17}$$

Then we have the following

Lemma 2. *The points λ_k, $k=1,\ldots,4$ are all distinct.*

Proof. The derivative $\frac{dz(\xi)}{d\xi}$ has simple zeros at the points (λ_k,γ_k), $k=1,\ldots,4$, on the Riemann surface defined by (3.12). Therefore, as a function of z, 2 branches of the function $\xi(z)$ behaves as

$$\xi(z)=\gamma_k\pm C_k(z-\lambda_k)^{\frac{1}{2}}+O(z-\lambda_k),\quad z\rightarrow\lambda_k,$$

near the points λ_k. Let $i\neq j$, then Since $\gamma_i\neq\gamma_j$, if $\lambda_i=\lambda_j$, there will be 4 distinct solutions $\xi(z)$ to the equation (3.12) in a neighborhood of the point $\lambda_i=\lambda_j$, which is not possible. Therefore λ_i and λ_j are distinct. □

In particular, the points λ_3 and λ_4 are complex.

Lemma 3. *The points λ_3 and λ_4 are not real.*

Proof. Since $\gamma_3=\overline{\gamma}_4$, we see that $\lambda_3=\overline{\lambda}_4$. If λ_3 and λ_4 are real, then we will have $\lambda_3=\lambda_4$. This contradicts Lemma 2 and hence the points λ_3 and λ_4 are not real. □

We will label the points γ_3 and γ_4 such that $\mathrm{Im}(\lambda_3)>0$.

Note that, from the behavior of $z(\xi)$ in (3.11), we see that near the points -1 and $-\frac{1}{a}$, the function $z(\xi)$ behaves as

$$\begin{aligned}z(\xi)&=\frac{c(1-\beta)}{1+\xi}+O(1),\quad \xi\rightarrow-1,\\ z(\xi)&=\frac{ca\beta}{1+a\xi}+O(1),\quad \xi\rightarrow-\frac{1}{a}.\end{aligned}\tag{3.18}$$

and hence $z'(\xi)$ is negative near these points. From this and (3.15), we see that $z'(\xi)>0$ on the intervals $(-\infty,\gamma_1)$, $(\gamma_2,0)$ and $(0,\infty)$ and none of the points -1 or $-\frac{1}{a}$ belongs to these intervals. On (γ_1,γ_2), $z'(\xi)$ is negative.

The images of these intervals under the map (3.11) then give us the complement of $\mathrm{supp}(\underline{F})$ in the z-plane. Let us study these images

Lemma 4. *The intervals* $(-\infty,\gamma_1)$, $(\gamma_2,0)$ *and* $(0,\infty)$ *are mapped by* $z(\xi)$ *to* $(0,\lambda_1)$, (λ_2,∞) *and* $(-\infty,0)$ *respectively.*

Proof. Since none of the points -1, $-\frac{1}{a}$ and 0 belongs to these intervals both $z(\xi)$ and $z'(\xi)$ are continuous on these intervals. Moreover, $z(\xi)$ is strictly increasing on these intervals. Therefore the images of these intervals are given by

$$\begin{aligned}
z\left((-\infty,\gamma_1)\right) &= (z(-\infty),z(\gamma_1)) = (0,\lambda_1)\\
z\left((\gamma_2,0)\right) &= (z(\gamma_2),z(0^-)) = (\lambda_2,\infty)\\
z\left((0,\infty)\right) &= (z(0^+),z(\infty)) = (-\infty,0).
\end{aligned}$$

where the $\pm$ superscripts in the above indicates that the function is evaluated at $\pm\epsilon$ for $\epsilon\rightarrow 0$. □

Therefore the complement of $\mathrm{supp}(\underline{F})$ is given by (recall that $\underline{F}$ has a point mass at 0)

$$\mathrm{supp}(\underline{F})^c = (-\infty,0)\cup(0,\lambda_1)\cup(\lambda_2,\infty). \tag{3.19}$$

Let us now show that $\lambda_1<\lambda_2$. This would imply the support of $\underline{F}$ is non-empty and consists of one interval.

Lemma 5. *Let* λ_1 *and* λ_2 *be the points defined by (3.17), then* $\lambda_1<\lambda_2$ *and hence the support of* $\underline{F}$ *consists of a single interval.*

Proof. Suppose $\lambda_1>\lambda_2$. Let $z_0\in(\lambda_2,\lambda_1)$. Since both the points -1 and $-\frac{1}{a}$ belongs to (γ_1,γ_2), the function $z(\xi)$ is continuous in $(-\infty,\gamma_1)$ and $(\gamma_2,0)$. By Lemma 4, these two intervals are mapped onto $(0,\lambda_1)$ and (λ_2,∞) by the map $z(\xi)$. Hence there is at least one point in each of the intervals $(-\infty,\gamma_1)$ and $(\gamma_2,0)$ that is being mapped onto z_0. On the other hand, let s_1 and s_2 be the points in $\{-1,-\frac{1}{a}\}$ that is closer to γ_1 and γ_2 respectively, then $z(\xi)$ is continuous in (γ_1,s_1) and (s_2,γ_2). Since these intervals are mapped onto $(-\infty,\lambda_1,)$ and (λ_2,∞) respectively by $z(\xi)$, there is at least one point in each of these intervals that is mapped onto z_0. This would result in 4 distinct points being mapped onto z_0 by the map $z(\xi)$, which is not possible. Therefore we have $\lambda_1<\lambda_2$. □

Therefore we have the following

Theorem 5. *Let* Δ *be the discriminant of the quartic polynomial*

$$\begin{aligned}
&a^2(1-c)\xi^4 + 2(a^2(1-c\beta)+a(1-c(1-\beta))\xi^3\\
&\qquad + (1-c(1-\beta)+a^2(1-c\beta)+4a)\xi^2 + 2(1+a)\xi + 1 = 0.
\end{aligned} \tag{3.20}$$

then if $\Delta<0$, *the support of* $\underline{F}$ *consists of a single interval.*

We can treat (3.12) as a polynomial in ξ then λ_k, $k = 1, \dots, 4$ are the zeroes of its discriminant $D_3(z) = (az)^4 \prod_{i<j}(\xi_i - \xi_j)^2$.

$$\begin{aligned} D_3(z) = {} & (1-a)^2 z^4 + (2A_2^2 B_1 + 2A_2 B_2 - 4A_2^3 - 12aB_1 + 18aA_2) z^3 \\ & + (B_2^2 + A_2^2 B_1^2 + 4A_2 B_1 B_2 - 12A_2^2 B_2 - 12aB_1^2 + 18aB_2 + 18aA_2 B_1 - 27a^2) z^2 \\ & + (2B_1 B_2^2 + 2A_2 B_2 B_1^2 - 12A_2 B_2^2 - 4B_1^3 a + 18aB_1 B_2) z + B_1^2 B_2^2 - 4B_2^3. \end{aligned} \tag{3.21}$$

The zeros of (3.21) then correspond to the branch points of the Riemann surface $\mathcal{L}$. These branch points are given on $\mathcal{L}$ by (λ_k, γ_k), for $k = 1, \dots, 4$.

Since the leading coefficient of $D_3(z)$ is $(1-a)^2 > 0$, we see that the sign of $D_3(z)$ and hence the 3 roots of the cubic polynomial (3.12) behave as follows for $z \in \mathbb{R}$.

$$\begin{aligned} &1. \quad z \in \mathbb{R} \setminus [\lambda_1, \lambda_2], \quad D_3(z) > 0 \Rightarrow \xi \text{ has 3 distinct real roots} \\ &2. \quad z \in (\lambda_1, \lambda_2), \quad D_3(z) < 0 \Rightarrow \xi \text{ has 1 real and 2 complex roots.} \end{aligned} \tag{3.22}$$

In particular, since the roots coincide at the branch points, the γ_k, $k = 1, \dots, 4$ is the values of the double root of the cubic (3.12) when $z = \lambda_k$.

We can now compute the probability density $\underline{F}$.

Theorem 6. *Suppose $\Delta < 0$. Then the p.d.f $\underline{F}$ is supported on $[\lambda_1, \lambda_2]$ with the following density $d\underline{F}(z) = \rho(z)dz$*

$$\frac{3}{2\pi} \left| \left(\frac{r(z) + \sqrt{-\frac{1}{27a^4z^4} D_3(z)}}{2} \right)^{\frac{1}{3}} - \left(\frac{r(z) - \sqrt{-\frac{1}{27a^4z^4} D_3(z)}}{2} \right)^{\frac{1}{3}} \right|, \tag{3.23}$$

where $D_3(z)$ is given by (3.21) and $r(z)$ is given by

$$\begin{aligned} r(z) = \frac{1}{27} \Bigg(& -\frac{2B_2^3}{a^3} z^{-3} + \left(\frac{9B_1 B_2}{a^2} - \frac{6A_2 B_2^2}{a^3} \right) z^{-2} + \left(\frac{9B_2}{a^2} + \frac{9B_1 A_2}{a^2} - \frac{27}{a} - \frac{6A_2^2 B_2}{a^3} \right) z^{-1} \\ & + \left(\frac{9A_2}{a^2} - \frac{2A_2^3}{a^3} \right) \Bigg). \end{aligned}$$

The cube root in (3.23) is chosen such that $\sqrt[3]{A} \in \mathbb{R}$ for $A \in \mathbb{R}$ and the square root is chosen such that $\sqrt{A} > 0$ for $A > 0$.

The proof of this theorem is the same as Theorem 6 in [28].

Let us now show that the function $\xi_1(z)$ is in fact the Stieltjes transform $m_{\underline{F}}(z)$. From the asymptotic behavior of the $\xi_j(z)$ (1.17) and the fact that the Stieltjes transform $m_{\underline{F}}(z)$ is the unique solution of (3.12) that vanishes as $z \to \infty$, we see that

$$m_{\underline{F}}(z) = \xi_1(z). \tag{3.24}$$

For $c < 1$, it was shown in [15] that F has a continuous density and hence the Stieltjes transform $m_F(z)$ does not have any poles. Therefore, by (3.7), we see that $m_{\underline{F}}(z)$, and hence $\xi_1(z)$, has the following singularity at $z = 0$.

$$\xi_1(z) = -\frac{1-c}{z} + O(1), \quad z \to 0. \tag{3.25}$$

Since $m_{\underline{F}}(z)$ is the Stieltjes transform of a measure supported on the real axis, it is analytic away from the real axis and hence by (3.24), $\xi_1(z)$ is analytic at the points λ_3 and λ_4 with a branch cut on $[\lambda_1, \lambda_2]$. Since λ_3, λ_4 are not branch points of the function $\xi_1(z)$, they must be branch points of the functions $\xi_2(z)$ and $\xi_3(z)$. This determines the branch structure of the Riemann surface $\mathcal{L}$. The branch cut of $\xi_2(z)$ and $\xi_3(z)$ will eventually be chosen to be a contour that goes from λ_4 to λ_3 intersecting the real axis at a point in (λ_1, λ_2), but in the next section it will be chosen in a few different ways according to the situation.

3.2.1 Geometry of the problem

As explained in the introduction, the determination of the zero set of $h(x)$ in (1.18) is considerably more difficult than it is in [12] and [26]. In this section we will carry out a thorough analysis of this set and determine its topology.

For the implementation of the Riemann-Hilbert analysis, it is more convenient to consider a measure $\hat{F}_N$ instead of the measure $\underline{F}$.

Let $c_N = \frac{N}{M}$ and $H_N(t)$ be the e.d.f

$$dH_N(t) = (1-\beta_N)\delta_1 + \beta_N \delta_a.$$

where $\beta_N = \frac{N_1}{N}$.

Then $\hat{F}_N$ is the measure whose Stieltjes transform $m_N(z) = m_{\hat{F}_N}(z)$ is the unique solution of

$$z(m_N) = -\frac{1}{m_N} + c_N \int_{\mathbb{R}} \frac{t}{1+tm_N} dH_N(t), \tag{3.26}$$

in $\mathbb{C}^+$ that behaves like $-\frac{1}{z}$ as $z \to \infty$. Note that, as pointed out in [8], the measure $\hat{F}_N$ is not the eigenvalue distribution for finite N, instead, it is only defined through the equation (3.26). From (3.26), we see that $m_N(z)$ is the solution of the algebraic equation

$$\begin{aligned} &za\xi^3 + (A_2 z + B_2^N)\xi^2 + (z + B_1^N)\xi + 1 = 0, \\ &B_2^N = a(1-c_N), \quad B_1^N = 1 - c_N(1-\beta_N) + a(1-c_N\beta_N). \end{aligned} \tag{3.27}$$

that behaves as $-\frac{1}{z}$ as $z \to \infty$. If we denote by $\xi_j^N(z)$ the solutions of (3.27) with asymptotic behavior (1.17), but with c and β replaced by c_N and β_N, then we have $\xi_1^N(z) = m_N(z)$. In [15], it was shown that the measure $\hat{F}_N$ has a continuous density on $\mathbb{R}_+$ and a point mass of size $1 - c_N$ at 0 and hence $\xi_1^N(z)$ also have the asymptotic behavior (3.25) near $z = 0$ with c replaced by c_N. By Remark 2, all the results in the previous section will remain valid for (3.27) and $\xi_j^N(z)$, with β and c replaced by β_N and c_N. We will denote the Riemann surface defined by (3.27) $\mathcal{L}_N$.

Let Δ_N be the determinant of the quartic polynomial (3.16)

$$\begin{aligned} &a^2(1-c_N)\xi^4 + 2(a^2(1-c_N\beta_N) + a(1-c_N(1-\beta_N))\xi^3 \\ &\qquad + (1-c_N(1-\beta_N) + a^2(1-c_N\beta_N) + 4a)\xi^2 + 2(1+a)\xi + 1 = 0 \end{aligned} \tag{3.28}$$

Since the determinant Δ of the quartic polynomial (3.16) is continuous in the parameters a, β and c, for large enough N, M and N_1, we can assume that the determinant $\Delta_N < 0$. Then let $\gamma_1^N < \gamma_2^N$ be the real roots of (3.28) and γ_3^N and γ_4^N be the complex conjugate roots of (3.28) and let $\lambda_1^N < \lambda_2^N$ and λ_3^N, λ_4^N be their images under the map $z(\xi)$ given in (3.26).

For the time being, we will choose the branch cut of $\xi_1^N(z)$ to be the interval $[\lambda_1^N, \lambda_2^N]$, and the branch cut between λ_3^N and λ_4^N to be a simple contour $\mathcal{C}$ that is symmetric with respect to the real axis and oriented upwards. Across $\mathcal{C}$, the two branches $\xi_2^N(z)$ and $\xi_3^N(z)$ change into each other. The branch cut $\mathcal{C}$ will be chosen such that it intersects the real axis at exactly one point x^* that is not equal to λ_1^N or λ_2^N.

We will now define the functions $\theta_j^N(z)$ to be the the integrals of $\xi_j^N(z)$.

$$\begin{aligned} &\theta_1^N(z) = \int_{\lambda_l^N}^z \xi_1^N(x)dx, \quad \theta_2^N(z) = \int_{\lambda_3^N}^z \xi_2^N(x)dx, \quad \theta_3^N(z) = \int_{\lambda_3^N}^z \xi_3^N(x)dx, \\ &\text{if } x^* < \lambda_2^N, \quad l = 2; \quad \text{if } x^* > \lambda_2^N, \quad l = 1. \end{aligned} \tag{3.29}$$

The integration paths of the above integrals are chosen as follows. If $x^* < \lambda_2^N$, then the integration path will not intersect the set $\mathcal{C} \cup (-\infty, \lambda_2^N)$ and if $x^* > \lambda_2^N$, then the integration path will not intersect the set $\mathcal{C} \cup (\lambda_1^N, \infty)$.

Then from (1.17), (3.13) and (3.25), we see that the integrals (3.29) have the following behavior at $z = \infty$ and $z = 0$.

$$\begin{aligned} &\theta_1^N(z) = -\log z + l_1^N + O\left(z^{-1}\right), \quad z \to \infty, \\ &\theta_1^N(z) = -(1-c_N)\log z + O\left(1\right), \quad z \to 0, \\ &\theta_2^N(z) = -z + c_N(1-\beta_N)\log z + l_2^N + O\left(z^{-1}\right), \quad z \to \infty, \\ &\theta_2^N(z) = O\left(1\right), \quad z \to 0, \\ &\theta_3^N(z) = -\frac{z}{a} + c_N\beta_N \log z + l_3^N + O\left(z^{-1}\right), \quad z \to \infty, \\ &\theta_3^N(z) = O\left(1\right), \quad z \to 0. \end{aligned} \tag{3.30}$$

for some constants l_1^N, l_2^N and l_3^N.

Then the set $\mathfrak{H}$ defined by

$$\mathfrak{H} = \left\{z \in \mathbb{C} | \quad \mathrm{Re}\left(\theta_2^N(z) - \theta_3^N(z)\right) = 0\right\} \tag{3.31}$$

is important to the Riemann-Hilbert analysis. Let us now study its properties. First note that it is symmetric across the real axis.

Lemma 6. *Let the branch cut $\mathcal{C}$ between λ_3^N and λ_4^N be a simple contour that is symmetric with respect to the real axis. Then the set $\mathfrak{H}$ in (3.31) is symmetric with respect to the real axis.*

Proof. Let us consider the transformation $z \mapsto \overline{z}$ and $\xi(z) \mapsto \overline{\xi}(\overline{z})$ in (3.27). This gives

$$\overline{z}a\overline{\xi}(\overline{z})^3 + (A_2\overline{z} + B_2^N)\overline{\xi}(\overline{z})^2 + (\overline{z} + B_1^N)\overline{\xi}(\overline{z}) + 1 = 0. \tag{3.32}$$

This means that if $\xi(z)$ is a solution to (3.27), then so is $\overline{\xi}(\overline{z})$. Since the functions $\overline{\xi}_j^N(\overline{z})$ is analytic away from $\mathcal{C}\cup[\lambda_1^N, \lambda_2^N]$, it must equal either of the functions $\xi_1^N(z)$, $\xi_2^N(z)$ or $\xi_3^N(z)$. By considering the behavior of $\overline{\xi}_j^N(\overline{z})$ near $z = \infty$ using (1.17), we see that $\overline{\xi}_j^N(\overline{z}) = \xi_j^N(z)$ for $j = 1, 2, 3$. Let $z_0 \in \mathfrak{H}$, then we have

$$\mathrm{Re}\left(\int_{\lambda_3^N}^{z_0} (\xi_2^N(x) - \xi_3^N(x))dx\right) = 0. \tag{3.33}$$

By taking the complex conjugation of (3.33) and making use of the fact that $\overline{\xi}_j^N(\overline{z}) = \xi_j^N(z)$ for $j = 2, 3$, we obtain

$$\mathrm{Re}\left(\int_{\lambda_4^N}^{\overline{z}_0} (\xi_2^N(x) - \xi_3^N(x))dx\right) = 0. \tag{3.34}$$

Let us now show that $\mathrm{Re}\left(\theta_2^N(\lambda_4^N) - \theta_3^N(\lambda_4^N)\right) = 0$. Consider an integration contour Γ from λ_3^N to λ_4^N that is symmetric with respect to $\mathbb{R}$. Then we have

$$\begin{aligned}\overline{\mathrm{Re}\left(\int_{\lambda_3^N}^{\lambda_4^N} \left(\xi_2^N(x) - \xi_3^N(x)\right) dx\right)} &= \mathrm{Re}\left(\int_{\lambda_4^N}^{\lambda_3^N} \left(\xi_2^N(x) - \xi_3^N(x)\right) dx\right)\\ &= -\mathrm{Re}\left(\int_{\lambda_3^N}^{\lambda_4^N} \left(\xi_2^N(x) - \xi_3^N(x)\right) dx\right),\end{aligned}$$

where we have used $\lambda_3^N = \overline{\lambda}_4^N$ in the above. Hence we have $\mathrm{Re}\left(\theta_2^N(\lambda_4^N) - \theta_3^N(\lambda_4^N)\right) = 0$. This implies the following

$$\mathrm{Re}\left(\int_{\lambda_4^N}^{\overline{z}_0} (\xi_2^N(x) - \xi_3^N(x))dx\right) = \mathrm{Re}\left(\int_{\lambda_3^N}^{\overline{z}_0} (\xi_2^N(x) - \xi_3^N(x))dx\right) = 0. \tag{3.35}$$

Therefore if $z_0 \in \mathfrak{H}$, then $\overline{z}_0$ is also in $\mathfrak{H}$ and hence $\mathfrak{H}$ is symmetric with respect to the real axis. ☐

We will now show that the set $\mathfrak{H}$ is independent on the choice of the branch cut $\mathcal{C}$.

Lemma 7. *Let the branch cut $\mathcal{C}$ be symmetric with respect to the real axis. Then the set $\mathfrak{H}$ is independent on the choice of the branch cut $\mathcal{C}$.*

Proof. Let us consider the boundary values of $\theta_2^N(z)$ and $\theta_3^N(z)$ along the branch cut $\mathcal{C}$. Let $\xi_{2,\pm}^N(z)$ and $\xi_{3,\pm}^N(z)$ be the boundary values of $\xi_2^N(z)$ and $\xi_3^N(z)$ on the left and right hand sides of $\mathcal{C}$, then we have $\xi_{2,\pm}^N(z) = \xi_{3,\mp}^N(z)$ for $z \in \mathcal{C}$. Therefore, for z in the upper half plane, we have the following

$$\int_{\lambda_3^N}^{z} (\xi_{2,+}^N(x) - \xi_{3,+}^N(x))dx = -\int_{\lambda_3^N}^{z} (\xi_{2,-}^N(x) - \xi_{3,-}^N(x))dx$$

where the integration is performed along $\mathcal{C}$. Therefore in the upper half plane, the function $\theta_2^N(z) - \theta_3^N(z)$ changes sign across the branch cut $\mathcal{C}$. Hence in the upper half plane, the zero set of $\mathrm{Re}\left(\theta_2^N(z) - \theta_3^N(z)\right)$ is independent on the choice of $\mathcal{C}$. Now by Lemma 6 the set $\mathfrak{H}$ is symmetric with respect to the real axis for any choice of symmetric branch cut $\mathcal{C}$. Therefore the set $\mathfrak{H}$ in the lower half plane is just the reflection of $\mathfrak{H}$ in the upper half plane which must also be independent on the choice of $\mathcal{C}$. ☐

We will now show that the real parts of $\xi_2^N(z)$ and $\xi_3^N(z)$ will coincide exactly once on the real axis.

Lemma 8. *Let x^* be the intersection between $\mathcal{C}$ and $\mathbb{R}$, then the real function $\mathrm{Re}\left(\xi_2^N(z) - \xi_3^N(z)\right)$ is continuous on $(-\infty, x^*)$ and (x^*, ∞) and it vanishes exactly once at a point $\iota \in \mathbb{R} \setminus \{x^*\}$.*

Proof. The location of x^* is immaterial as the function $\mathrm{Re}\left(\xi_2^N(z) - \xi_3^N(z)\right)$ only changes sign across the point x^* and hence its zeros on $\mathbb{R}$ are independent on the location of x^*. For definiteness, let us assume that $x^* < \lambda_1^N$.

Let $l_1 = 2$, $l_2 = 3$ for $a > 1$ and $l_1 = 3$, $l_2 = 2$ for $a < 1$. From the behavior (1.17) of $\xi_j^N(z)$ near $z = \pm\infty$, we see that there exists $R > 0$ such that $\xi_1^N(\pm R) > \xi_{l_2}^N(\pm R) > \xi_{l_1}^N(\pm R)$. Note that $\xi_{l_1}^N(z)$ and $\xi_{l_2}^N(z)$ are continuous on $(-\infty, x^*) \cup (\lambda_2^N, \infty)$. Since these intervals do not contain any branch point of (3.27) and both $\xi_{l_1}^N(z)$ and $\xi_{l_2}^N(z)$ are real on them, $\mathrm{Re}\left(\xi_{l_1}^N(z)\right)$ and $\mathrm{Re}\left(\xi_{l_2}^N(z)\right)$ cannot coincide on these intervals. In particular, the order $\xi_{l_2}^N(z) > \xi_{l_1}^N(z)$ must be preserved in $(-\infty, x^*) \cup (\lambda_2^N, \infty)$. Since $\xi_{l_1}^N(z)$ and $\xi_{l_2}^N(z)$ interchange across the branch cut $\mathcal{C}$, we must have $\xi_{l_1}^N(z) > \xi_{l_2}^N(z)$ in the interval (x^*, λ_1^N). This means that $\xi_{l_1}^N(z) > \xi_{l_2}^N(z)$ on the left hand side of $[\lambda_1^N, \lambda_2^N]$, while $\xi_{l_1}^N(z) < \xi_{l_2}^N(z)$ on the right hand side of $[\lambda_1^N, \lambda_2^N]$ and hence $\mathrm{Re}\left(\xi_2^N(z)\right)$ and $\mathrm{Re}\left(\xi_3^N(z)\right)$ must coincide at least once in $[\lambda_1^N, \lambda_2^N]$. We will show that they can only coincide once within $[\lambda_1^N, \lambda_2^N]$.

Inside $[\lambda_1^N, \lambda_2^N]$, the function $\xi_1^N(z)$ and one other root $\xi_I^N(z)$ becomes complex and are conjugate to each other, while another root $\xi_R^N(z)$ remains real. Note that, since $\xi_{I,\pm}^N(z) = \xi_{1,\mp}^N(z)$ on the branch cut $[\lambda_1^N, \lambda_2^N]$, we see that the real part of $\xi_I^N(z)$ and $\xi_1^N(z)$ is continuous across $[\lambda_1^N, \lambda_2^N]$, while $\xi_R^N(z)$ has no jump discontinuity across $[\lambda_1^N, \lambda_2^N]$. Since neither $\xi_I^N(z)$ or $\xi_R^N(z)$ are equal to the branch $\xi_1^N(z)$ in $(\lambda_1^N, \lambda_2^N)$, the real function $\mathrm{Re}\left(\xi_I^N(z) - \xi_R^N(z)\right)$ must equal either of $\pm\mathrm{Re}\left(\xi_2^N(z) - \xi_3^N(z)\right)$ and hence the real function $\mathrm{Re}\left(\xi_2^N(z) - \xi_3^N(z)\right)$ does not have jump discontinuity on $[\lambda_1^N, \lambda_2^N]$. Therefore for $z \in \mathbb{R}$, this real function can only have jump discontinuity at the point x^*.

From the coefficient of ξ^2 in (3.27), we see that

$$2\mathrm{Re}\left(\xi_I^N(z)\right) + \xi_R^N(z) = -\frac{1}{a}\left(A_2 + \frac{B_2^N}{z}\right). \tag{3.36}$$

Taking the derivative with respect to z, we obtain

$$2\frac{d}{dz}\mathrm{Re}\left(\xi_I^N(z)-\xi_R^N(z)\right)+3\frac{d\xi_R^N(z)}{dz}=\frac{1}{a}\frac{B_2^N}{z^2}.$$

This implies

$$3\frac{d\xi_R^N(z)}{dz}=\frac{1}{a}\frac{B_2^N}{z^2}-2\frac{d}{dz}\mathrm{Re}\left(\xi_I^N(z)-\xi_R(z)\right).$$

From (3.27), it is easy to see that $B_2^N>0$ as $c_N<1$. Hence if the derivative of $\mathrm{Re}\left(\xi_I^N(z)-\xi_R(z)\right)$ is non-positive at a point $z_0\in[\lambda_1^N,\lambda_2^N]$, then we will have $\frac{d\xi_R(z_0)}{dz}>0$. Since $\xi_R(z)$ is real, this would imply the derivative $\frac{dz(\xi)}{d\xi}$ of the function z defined by (3.26) is positive at the real point $m=\xi_R(z_0)$. By Lemma 1, the point $z_0=z(m)$ cannot belong to $\mathrm{Supp}\left(\hat{F}_N\right)=[\lambda_1^N,\lambda_2^N]$. This leads to a contradiction and hence we must have

$$\frac{d}{dz}\mathrm{Re}\left(\xi_I^N(z)-\xi_R^N(z)\right)>0,\quad z\in[\lambda_1^N,\lambda_2^N]. \tag{3.37}$$

In particular, if the function $\mathrm{Re}\left(\xi_I^N(z)-\xi_R^N(z)\right)$ has more than one zero inside of $[\lambda_1^N,\lambda_2^N]$, then at one of the zeros, the derivative in (3.37) must be smaller than or equal to zero. This is a contradiction and hence the function $\mathrm{Re}\left(\xi_I^N(z)-\xi_R^N(z)\right)$ can vanish at most once inside $[\lambda_1^N,\lambda_2^N]$. This means that the function $\mathrm{Re}\left(\xi_2^N(z)-\xi_3^N(z)\right)$ will also vanish at most once inside $[\lambda_1^N,\lambda_2^N]$. Since we have already shown that $\mathrm{Re}\left(\xi_2^N(z)-\xi_3^N(z)\right)$ vanishes at least once inside this interval, it must then vanish exactly once inside $[\lambda_1^N,\lambda_2^N]$. This concludes the proof of the lemma. ☐

We can now determine the number of intersection points between $\mathfrak{H}$ and $\mathbb{R}$.

Lemma 9. *The set* $\mathfrak{H}$ *intersects* $\mathbb{R}$ *at most twice.*

Proof. By Lemma 8, there exists exactly one point $\iota\in[\lambda_1^N,\lambda_2^N]$ such that $\mathrm{Re}\left(\xi_2^N(\iota)-\xi_3^N(\iota)\right)=0$. Let us assume that $\mathfrak{H}$ and $\mathbb{R}$ intersects at a point $s_0<\iota$. The case when $s_0>\iota$ can be treated similarly. Let us also choose $\mathcal{C}$ such that $\mathcal{C}$ intersects $\mathbb{R}$ at $x^*<s_0$. As both $\mathfrak{H}$ and ι are independent on the choice of $\mathcal{C}$, a different choice will not affect the intersection between $\mathfrak{H}$ and $\mathbb{R}$. Since $x^*<s_0$, the function $\mathrm{Re}\left(\xi_2^N-\xi_3^N\right)$ is continuous and has different signs on (s_0,ι) and (ι,∞). However, within these two intervals, the sign of $\mathrm{Re}\left(\xi_2^N-\xi_3^N\right)$ remains unchanged. Hence there is at most one point $z\in(s_0,\infty)$ such that $\mathrm{Re}\left(\int_{s_0}^z\xi_2^N-\xi_3^N dx\right)=0$, where the integration path is taken along $\mathbb{R}$. Since $\mathrm{Re}\left(\int_{\lambda_3^N}^{s_0}\xi_2^N-\xi_3^N dx\right)=0$ and that $\mathfrak{H}$ is symmetric with respect to the real axis, we see that there is at most one point on (s_0,∞) that belongs to $\mathfrak{H}$.

Let us now consider the possible intersection points on $(-\infty,s_0)$. As the choice of the branch cut $\mathcal{C}$ does not affect the set $\mathfrak{H}$ and its intersection with the real axis, let us choose $\mathcal{C}$ so that it intersects $\mathbb{R}$ at a point $\tilde{x}_0>s_0$ instead. Then $\mathrm{Re}\left(\xi_2^N-\xi_3^N\right)$ is continuous on $(-\infty, s_0)$. Moreover, it does not change sign in $(-\infty, s_0)$. Therefore the function $\mathrm{Re}\left(\int_{\lambda_3^N}^z \xi_2^N - \xi_3^N dx\right)$ does not vanish in $(-\infty, s_0)$ and hence $\mathfrak{H}$ does not intersect $(-\infty, s_0)$. This shows that if $\mathfrak{H}$ intersects $\mathbb{R}$ at a point $s_0 < \iota$, then there can at most be 2 intersection points between $\mathfrak{H}$ and $\mathbb{R}$. By using similar argument, one can show the same for the case when $s_0 > \iota$.

Let us now consider the case when $s_0 = \iota$. If $s_0 = \iota$, then by choosing $\mathcal{C}$ such that $x^* < \iota$ ($x^* > \iota$), we see that $\mathrm{Re}\left(\xi_2^N - \xi_3^N\right)$ does not change sign in (s_0, ∞) ($(-\infty, s_0)$) and hence $\mathrm{Re}\left(\int_{\lambda_3^N}^z \xi_2^N - \xi_3^N dx\right)$ does not vanish in either of these intervals. Therefore $\mathfrak{H}$ can only intersect $\mathbb{R}$ at the point $s_0 = \iota$. In any case, the set $\mathfrak{H}$ can intersect $\mathbb{R}$ at 2 points at most. $\square$

We can now determine the shape of the set $\mathfrak{H}$.

Proposition 2. *The set $\mathfrak{H}$ consists of 4 simple curves, $\mathfrak{H}_\infty^\pm$, $\mathfrak{H}_L$ and $\mathfrak{H}_R$. The curve $\mathfrak{H}_\infty^+$ ($\mathfrak{H}_\infty^-$) is an open smooth curve that go from λ_3^N (λ_4^N) to infinity. They approach infinity in a direction parallel to the imaginary axis and do not intersect the real axis. The curves $\mathfrak{H}_L$ and $\mathfrak{H}_R$ are simple curves joining λ_3^N and λ_4^N. The curve $\mathfrak{H}_L$ is in the left hand side of $\mathfrak{H}_R$ in the complex plane and each of these curves intersects the real axis once. These two curves are smooth except at their intersections with real axis. Let x_L and x_R be the intersection points of $\mathfrak{H}_L$ and $\mathfrak{H}_R$ with $\mathbb{R}$, then $(x_L, x_R) \cap [\lambda_1^N, \lambda_2^N] \neq \emptyset$.*

Proof. Let the sets $\mathfrak{H}_+$ and $\mathfrak{H}_-$ be the intersections of $\mathfrak{H}$ with the upper and lower half planes respectively. Then these 2 sets are reflections of each other with respect to the real axis. Within the set $\mathfrak{H}_+$, there are 3 curves $\mathfrak{H}_0^+$, $\mathfrak{H}_1^+$ and $\mathfrak{H}_2^+$ coming out of the point λ_3^N. Let us show that these curves are smooth except at λ_3^N. Suppose there is a point z_0 on $\mathfrak{H}_j^+$ that is not smooth. This means that the function $\theta_2^N - \theta_3^N$ is not conformal at z_0. Since $\mathfrak{H}$ is independent on the choice of the branch cut $\mathcal{C}$, by changing the branch cut if necessary, we can assume that both $\theta_2^N(z)$ and $\theta_3^N(z)$ are analytic at z_0 and therefore the derivative of $\theta_2^N - \theta_3^N$ must be zero at z_0 as the function is not conformal at z_0. This would imply $\xi_2^N(z_0) = \xi_3^N(z_0)$, which is impossible as the only points where this happens are the points λ_k^N. Therefore the curves $\mathfrak{H}_j^+$, $j = 0, 1, 2$ are smooth except at the point λ_3^N.

We will now show that the curves $\mathfrak{H}_j^+$ cannot be connected with one another except at the point λ_3^N. Suppose the curves $\mathfrak{H}_j^+$ is connected to $\mathfrak{H}_k^+$ at a point $z_0 \neq \lambda_3^N$. Since both curves $\mathfrak{H}_j^+$ and $\mathfrak{H}_k^+$ are smooth, the curve $\mathfrak{H}_j^+ \cup \mathfrak{H}_k^+$ forms a close loop in the upper half plane. Let V be the region bounded by this close loop. Then by changing the choice of $\mathcal{C}$ if necessary, we can assume that the functions $\theta_2^N(z)$ and $\theta_3^N(z)$ are analytic in the interior of V. Then the function $\mathrm{Re}\left(\theta_2^N - \theta_3^N\right)$ is a harmonic function in the interior of V and has constant value at the boundary of V. Therefore, by the maximum modulus principle this function must be a constant in V. This is not possible and hence the curves $\mathfrak{H}_j^+$ cannot be connected to each other.

By inspecting the behavior of $\theta_2^N - \theta_3^N$ at $z = \infty$, we see that one of these curves must be an open curve that approaches infinity at a direction parallel to the imaginary axis. We

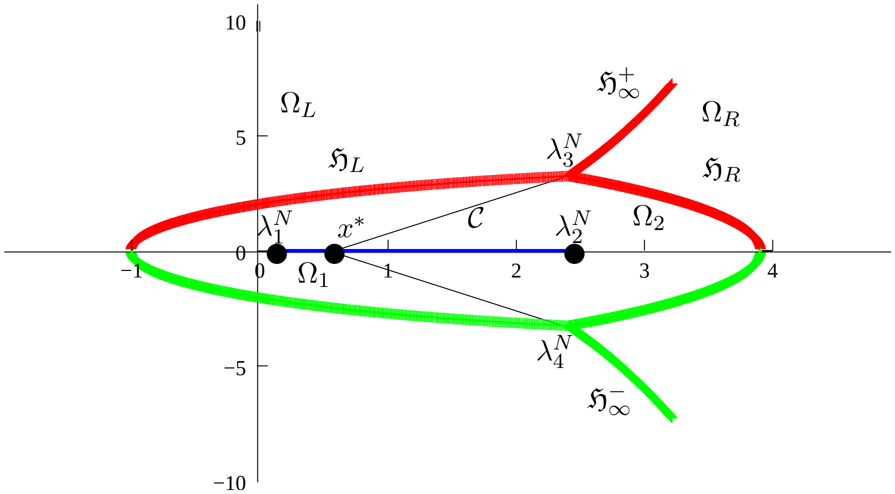

Figure 2: The set $\mathfrak{H}$ for $a = 0.9$, $\beta_N = 0.7$ and $c_N = 0.4$. The branch points are given by $\lambda_1^N \approx 0.12518$, $\lambda_2^N \approx 2.48841$, $\lambda_3^N \approx 2.40520 + 3.2516i$ and $\lambda_4^N \approx 2.40520 - 3.2516i$. The point ι in Lemma 8 is given by $\iota \approx 0.602$. For $a < 1$, the function $\mathrm{Re}\left(\theta_2^N(z) - \theta_3^N(z)\right)$ is negative in the open region Ω_L on the left of $\mathfrak{H}_L$ and positive in the region Ω_R on the right hand side of $\mathfrak{H}_R$.

will call this curve $\mathfrak{H}^+_\infty$ and its reflection with respect to the real axis $\mathfrak{H}^-_\infty$. Since the other 2 curves cannot intersect each other, and they cannot go to infinity either, they must end at the real axis and be connected to the curves in $\mathfrak{H}^-$. We will call the curve on the left hand side $\mathfrak{H}^+_L$ and the one on the right hand side $\mathfrak{H}^+_R$. These two curves must end at different points on the real axis as they cannot intersect. Let us denote the curves $\mathfrak{H}_L$ and $\mathfrak{H}_R$ by

$$\begin{aligned} \mathfrak{H}_L &= \mathfrak{H}^+_L \cup \mathfrak{H}^-_L \cup \{x_L\}, \\ \mathfrak{H}_R &= \mathfrak{H}^+_R \cup \mathfrak{H}^-_R \cup \{x_R\}. \end{aligned} \tag{3.38}$$

where $\mathfrak{H}^-_L$ and $\mathfrak{H}^-_R$ are the reflections of $\mathfrak{H}^+_L$ and $\mathfrak{H}^+_R$ with respect to the real axis and x_L, x_R are their accumulation points on the real axis.

Let us now show that

$$\mathfrak{H}^+ = \mathfrak{H}^+_\infty \cup \mathfrak{H}^+_L \cup \mathfrak{H}^+_R. \tag{3.39}$$

Suppose there is a point $z_1 \in \mathfrak{H}^+$ that does not belong to any of the curves in the right hand side of (3.39). Then z_1 must belong to a curve $\mathfrak{H}^+_4 \in \mathfrak{H}^+$. By changing the definition of $\mathcal{C}$ again if necessary, we see that $\mathfrak{H}^+_4$ must be smooth. This curve cannot end on the real axis because by Lemma 9, the set $\mathfrak{H}$ can at most intersect the real axis at 2 points and $\mathfrak{H}$ has already intersected the real axis at the 2 points x_L and x_R in (3.38). The curve $\mathfrak{H}^+_4$ cannot approach infinity or intersect any other curves in $\mathfrak{H}^+$ either and therefore it must be a close loop in the upper half plane. As $\mathfrak{H}^+_4$ cannot intersect the curves in the right hand side of (3.39), the point λ_3^N must lie outside of the region $\tilde{V}$ bounded by $\mathfrak{H}^+_4$. This would then imply that the harmonic function $\mathrm{Re}\left(\theta_2^N - \theta_3^N\right)$ is constant inside the region

$\tilde{V}$, which is not possible and hence we have

$$\mathfrak{H} = \mathfrak{H}_\infty^+ \cup \mathfrak{H}_\infty^- \cup \mathfrak{H}_L \cup \mathfrak{H}_R.$$

Finally, if $(x_L, x_R) \cap [\lambda_1^N, \lambda_2^N] = \emptyset$, then the function $\mathrm{Re}\left(\theta_2^N - \theta_3^N\right)$ is harmonic inside the region bounded by $\mathfrak{H}_L$ and $\mathfrak{H}_R$, which is not possible as it would imply that it is a constant function in this region. This concludes the proof of the proposition. □

The shape of the set $\mathfrak{H}$ is indicated in Figure 2. The Octave generated figure shows the set for $a = 0.9$, $\beta_N = 0.7$ and $c_N = 0.4$.

3.2.2 Jump discontinuities of the functions

From now on, we will choose the branch cut $\mathcal{C}$ to be a simple curve joining λ_3^N and λ_4^N that is symmetric with respect to the real axis. We also require $\mathcal{C}$ to lie between the curves $\mathfrak{H}_L$ and $\mathfrak{H}_R$ in Proposition 2 and that it intersects $\mathbb{R}$ at a point $\lambda_1^N < x^* < \lambda_2^N$. The integration contours for the functions $\theta_j^N(z)$ in (3.29) are chosen such that they do not intersect the set $(-\infty, \lambda_2^N) \cup \mathcal{C}$ and the point λ_l^N in (3.29) is chosen to be λ_2^N.

Proposition 3. *If $a > 1$, then λ_2^N is a branch point of $\xi_3^N(z)$ and λ_1^N is a branch point of $\xi_2^N(z)$. On the other hand, if $a < 1$, then λ_1^N is a branch point of $\xi_3^N(z)$ while λ_2^N is a branch point of $\xi_2^N(z)$.*

Proof. Let $l_1 = 2$, $l_2 = 3$ for $a > 1$ and $l_1 = 3$, $l_2 = 2$ for $a < 1$. Then for large enough $z_0 > \lambda_2^N$, all the functions ξ_j^N are real and we have $\xi_1^N(z_0) > \xi_{l_2}^N(z_0) > \xi_{l_1}^N(z_0)$ by (1.17). This ordering must preserve at λ_2^N as the roots cannot coincide between z_0 and λ_2^N. At λ_2^N, one of the roots must coincide with ξ_1^N and from the ordering $\xi_1^N(z_0) > \xi_{l_2}^N(z_0) > \xi_{l_1}^N(z_0)$, we must have $\xi_1^N(\lambda_2^N) = \xi_{l_2}^N(\lambda_2^N) = \gamma_2^N$. On the other hand, for small enough $0 < \epsilon < \lambda_1^N$, all three ξ_j^N will be real. From the asymptotic behavior of $\xi_1^N(z)$ at 0 (3.25), we see that for small enough ϵ, $\xi_1^N(\epsilon)$ will be smaller than both $\xi_2^N(\epsilon)$ and $\xi_3^N(\epsilon)$. From the asymptotic behavior of ξ_2^N and ξ_3^N at $z = -\infty$ (1.17) and the fact that these 2 functions has no singularity and cannot coincide in $(-\infty, \lambda_1^N)$, we see that at $z = \epsilon$, we must have $\xi_{l_2}^N(\epsilon) > \xi_{l_1}^N(\epsilon)$. Therefore we have $\xi_{l_2}^N(\epsilon) > \xi_{l_1}^N(\epsilon) > \xi_1^N(\epsilon)$. This ordering must again be preserved at λ_1^N. Therefore we must have $\xi_1^N(\lambda_1^N) = \xi_{l_1}^N(\lambda_1^N) = \gamma_1^N$. This shows that λ_2^N is a branch point of $\xi_{l_2}^N$ while λ_1^N is a branch point of $\xi_{l_1}^N$. □

We can now determine the jump discontinuities of ξ_j^N on the branch cuts

$$\begin{aligned} &\xi_{1,\pm}^N(z) = \xi_{2,\mp}^N(z), \quad z \in \mathfrak{B}_{k_2}, \quad \xi_{1,\pm}^N(z) = \xi_{3,\mp}^N(z), \quad z \in \mathfrak{B}_{k_3}, \\ &\xi_{2,\pm}^N(z) = \xi_{3,\mp}^N(z), \quad z \in \mathcal{C}. \end{aligned} \tag{3.40}$$

where $k_2 = 1$, $k_3 = 2$ for $a > 1$ and $k_2 = 2$, $k_3 = 1$ for $a < 1$ and $\mathfrak{B}_j$ are defined by

$$\mathfrak{B}_1 = [\lambda_1^N, x^*), \quad \mathfrak{B}_2 = (x^*, \lambda_2^N]. \tag{3.41}$$

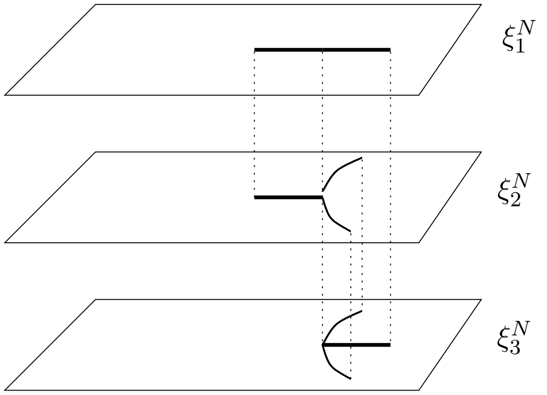

Figure 3: The branch cut structure of the Riemann surface $\mathcal{L}_N$ when $a > 1$.

The branch cut structure of the Riemann surface $\mathcal{L}_N$ is indicated in Figure 3.

Let us define $\tilde{\theta}_j^N(z)$ to be constant shifts of the $\theta_j^N(z)$.

$$\begin{aligned}
&\tilde{\theta}_1^N(z) = \theta_1^N(z);\\
&\tilde{\theta}_2^N(z) = \begin{cases} \theta_2^N(z) - \theta_{2,+}^N(\lambda_1^N) + \theta_{1,-}^N(\lambda_1^N), & a > 1;\\ \theta_2^N(z) - \theta_{2,+}^N(\lambda_2^N), & a < 1.\end{cases}\\
&\tilde{\theta}_3^N(z) = \begin{cases} \theta_3^N(z) - \theta_{3,+}^N(\lambda_2^N), & a > 1;\\ \theta_3^N(z) - \theta_{3,+}^N(\lambda_1^N) + \theta_{1,-}^N(\lambda_1^N), & a < 1.\end{cases}
\end{aligned} \tag{3.42}$$

Note that the difference between $\theta_2^N(z)$ and $\theta_3^N(z)$ are the same as the difference between $\tilde{\theta}_2^N(z)$ and $\tilde{\theta}_3^N(z)$.

Lemma 10. *Let $\tilde{\theta}_j^N(z)$ be defined as in (3.42), then we have $\theta_2^N(z)-\theta_3^N(z) = \tilde{\theta}_2^N(z)-\tilde{\theta}_3^N(z)$. If $z \in (-\infty, \lambda_2^N) \cup \mathcal{C}$, then we also have*

$$\begin{aligned}
&\theta_{2,\pm}^N(z) - \theta_{3,\pm}^N(z) - \left(\tilde{\theta}_{2,\pm}^N(z) - \tilde{\theta}_{3,\pm}^N(z)\right) = 0,\\
&\theta_{2,\pm}^N(z) - \theta_{3,\mp}^N(z) - \left(\tilde{\theta}_{2,\pm}^N(z) - \tilde{\theta}_{3,\mp}^N(z)\right) = 0
\end{aligned} \tag{3.43}$$

where the '+' and '−' subscripts indicates the boundary values on the left and right hand sides of $(-\infty, \lambda_2^N) \cup \mathcal{C}$.

Proof. Let $l_1 = 2$, $l_2 = 3$ when $a > 1$ and $l_1 = 3$, $l_2 = 2$ when $a < 1$. Then from (3.42), we have

$$\tilde{\theta}_2^N(z) - \tilde{\theta}_3^N(z) - \left(\theta_2^N(z) - \theta_3^N(z)\right) = (-1)^{l_1+1}\left(\theta_{l_1,+}^N(\lambda_1^N) - \theta_{l_2,+}^N(\lambda_2^N) - \theta_{1,-}^N(\lambda_1^N)\right). \tag{3.44}$$

From (3.42), it is clear that if $z \in (-\infty, \lambda_2^N) \cup \mathcal{C}$, then the differences in (3.43) are also given by the constant on the right hand side of (3.44).

Let us consider the difference $\theta_{l_1,+}^N(\lambda_1^N)-\theta_{l_2,+}^N(\lambda_2^N)$. We will compute $\theta_{l_1,+}^N(\lambda_1^N)$ ($\theta_{l_2,+}^N(\lambda_2^N)$) with an integration path that consists of 2 parts. The first part goes along the left (right) hand side of $\mathcal{C}$ from λ_3^N to x^*. The second part goes along the positive side of the real axis from x^* to λ_1^N (λ_2^N). We then have

$$\begin{aligned}\theta_{l_1,+}^N(\lambda_1^N) &= \int_{\lambda_3^N}^{x^*} \xi_{l_1,+}^N(x)dx + \int_{x^*}^{\lambda_1^N} \xi_{l_1,+}^N(x)dx,\\ \theta_{l_2,+}^N(\lambda_2^N) &= \int_{\lambda_3^N}^{x^*} \xi_{l_2,-}^N(x)dx + \int_{x^*}^{\lambda_2^N} \xi_{l_2,+}^N(x)dx\end{aligned} \tag{3.45}$$

From (3.40), we see that $\xi_{l_1,+}^N = \xi_{l_2,-}^N$ along $\mathcal{C}$ and $\xi_{l_1,+}^N(x) = \xi_{1,-}^N(x)$ along (x^*, λ_1^N), while $\xi_{l_2,+}^N(x) = \xi_{1,-}^N(x)$ along (x^*, λ_2^N). From this and (3.45), we obtain

$$\theta_{l_1,+}^N(\lambda_1^N) - \theta_{l_2,+}^N(\lambda_2^N) = \int_{\lambda_2^N}^{\lambda_1^N} \xi_{1,-}^N(x)dx = \theta_{1,-}^N(\lambda_1^N), \tag{3.46}$$

where the last inequality follows from the fact that $\xi_1^N(z)$ is analytic across $\mathcal{C}$ and hence we can choose the integration path for $\theta_1^N(\lambda_1^N)$ to be along the real axis.

From (3.46), we see that $\theta_{l_1,+}^N(\lambda_1^N) - \theta_{l_2,+}^N(\lambda_2^N) - \theta_{1,-}^N(\lambda_1^N) = 0$ and hence $\theta_2^N(z) - \theta_3^N(z) = \tilde{\theta}_2^N(z) - \tilde{\theta}_3^N(z)$. □

From the behavior of $\xi_j^N(z)$ on the cuts, we have the following analyticity properties of the $\tilde{\theta}_j^N(z)$.

Lemma 11. *The function $\tilde{\theta}_1^N(z)$ is analytic on $\mathbb{C}\backslash(-\infty, \lambda_2^N]$. The function $\tilde{\theta}_2^N(z)$ ($\tilde{\theta}_3^N(z)$) is analytic on $\mathbb{C}\backslash((-\infty, x^*] \cup \mathcal{C})$ when $a > 1$ ($a < 1$) and it is analytic on $\mathbb{C}\backslash\big((-\infty, \lambda_2^N] \cup \mathcal{C}\big)$ when $a < 1$ ($a > 1$). Let $k_2 = 1$, $k_3 = 2$ for $a > 1$ and $k_2 = 2$, $k_3 = 1$ for $a < 1$. Let $\mathcal{C}_\pm$ are the intersections of $\mathcal{C}$ with the upper/lower half planes. Then the integrals $\tilde{\theta}_j^N(z)$ have the following jump discontinuities.*

$$\begin{aligned}
&\tilde{\theta}_{1,\pm}^N(z) = \tilde{\theta}_{j,\mp}^N(z) + \upsilon_\pm, , \quad z \in \mathfrak{B}_{k_j}, \quad j = 2,3,\\
&\tilde{\theta}_{2,\pm}^N(z) = \tilde{\theta}_{3,\mp}^N(z), \quad z \in \mathcal{C}_+,\\
&\tilde{\theta}_{2,\pm}^N(z) = \tilde{\theta}_{3,\mp}^N(z) + 2c_N\beta_N\pi i, \quad a > 1, \quad z \in \mathcal{C}_-,\\
&\tilde{\theta}_{2,\pm}^N(z) = \tilde{\theta}_{3,\mp}^N(z) - 2c_N(1-\beta_N)\pi i, \quad a < 1, \quad z \in \mathcal{C}_-,\\
&\tilde{\theta}_{1,+}^N(z) = \tilde{\theta}_{1,-}^N(z) - 2c_N\pi i, \quad z \in (0, \lambda_1^N],\\
&\tilde{\theta}_{1,+}^N(z) = \tilde{\theta}_{1,-}^N(z) - 2\pi i, \quad z \in (-\infty, 0),\\
&\tilde{\theta}_{2,+}^N(z) = \tilde{\theta}_{2,-}^N(z) + 2c_N(1-\beta_N)\pi i, \quad z \in (-\infty, \lambda_1^N],\\
&\tilde{\theta}_{2,+}^N(z) = \tilde{\theta}_{2,-}^N(z) + 2c_N(1-\beta_N)\pi i, \quad z \in \mathfrak{B}_1, \quad a < 1,\\
&\tilde{\theta}_{3,+}^N(z) = \tilde{\theta}_{3,-}^N(z) + 2c_N\beta_N\pi i, \quad z \in (-\infty, \lambda_1^N],\\
&\tilde{\theta}_{3,+}^N(z) = \tilde{\theta}_{3,-}^N(z) + 2c_N\beta_N\pi i, \quad z \in \mathfrak{B}_1, \quad a > 1.
\end{aligned} \tag{3.47}$$

where $\upsilon_{\pm}$ is the constant

$$\upsilon_{\pm} = \theta_{j,+}\left(\lambda_{k_j}^N\right) - \theta_{j,\mp}\left(\lambda_{k_j}^N\right) + \theta_{1,\pm}\left(\lambda_{k_j}^N\right) - \theta_{1,-}\left(\lambda_{k_j}^N\right). \tag{3.48}$$

and $\mathfrak{B}_j$ is defined in (3.41). In particular, by the jump discontinuities of the $\tilde{\theta}_j^N(z)$ at the points λ_k^N, and the fact that $\theta_j^N(z)$ and $\tilde{\theta}_j^N(z)$ differs by a constant shift only, we see that the constant $\upsilon_{\pm}$ is either $-2c_N\beta_N\pi i$, $-2c_N(1-\beta_N)\pi i$ or 0.

Proof. From the jump discontinuities of $\xi_j^N(z)$ in (3.40), we see that

$$\begin{aligned}
\left(\int_{\lambda_{k_j}^N}^z \xi_1^N(x)dx\right)_{\pm} &= \left(\int_{\lambda_{k_j}^N}^z \xi_j^N(x)dx\right)_{\mp}, \quad z \in \mathfrak{B}_{k_j}, \quad j = 2,3\\
\left(\int_{\lambda_3^N}^z \xi_2^N(x)dx\right)_{\pm} &= \left(\int_{\lambda_3^N}^z \xi_3^N(x)dx\right)_{\mp}, \quad z \in \mathcal{C}_+,\\
\left(\int_{\lambda_4^N}^z \xi_2^N(x)dx\right)_{\pm} &= \left(\int_{\lambda_4^N}^z \xi_3^N(x)dx\right)_{\mp}, \quad z \in \mathcal{C}_-.
\end{aligned}$$

The path of integration in the first equation is taken along the real axis and the integration paths in the last 2 equations are taken along $\mathcal{C}$. By comparing this with (3.29) and (3.42) and making use of Lemma 10, we obtain the first two equations in (3.47), together with

$$\tilde{\theta}_{2,\pm}^N(z) = \tilde{\theta}_{3,\mp}^N(z) + \theta_2^N(\lambda_4^N) - \theta_3^N(\lambda_4^N), \quad z \in \mathcal{C}_-. \tag{3.49}$$

Let us now compute the constant $\theta_2^N(\lambda_4^N) - \theta_3^N(\lambda_4^N)$. Let $l_1 = 2$, $l_2 = 3$ when $a > 1$ and $l_1 = 3$, $l_2 = 2$ when $a < 1$. Then $\xi_{l_1}^N$ will be analytic on $(x^*, \lambda_2^N]$ and hence we can compute $\theta_{l_1}^N(\lambda_4^N)$ using a contour that goes along the right hand side of $\mathcal{C}$. That is, we have

$$\theta_{l_1}^N(\lambda_4^N) = \int_{\lambda_3^N}^{\lambda_4^N} \xi_{l_1,-}^N(x)dx. \tag{3.50}$$

where the integration is performed along $\mathcal{C}$. To compute $\theta_{l_2}^N(\lambda_4^N)$, let us choose an integration contour as follows. The integration contour consists of three parts. The first part goes from λ_3^N to x^* on the left hand side of $\mathcal{C}$. The second part is a closed loop $\mathcal{S}$ that goes from x^* to x^* with the branch cut $\mathfrak{B}_2 \cup \mathcal{C}$ of $\xi_{l_2}^N$ inside it. The last part goes from x^* to λ_4^N along the left hand side of $\mathcal{C}$. That is, we have

$$\theta_{l_2}^N(\lambda_4^N) = \int_{\lambda_3^N}^{x^*} \xi_{l_2,+}^N(x)dx + \oint_{\mathcal{S}} \xi_{l_2}^N(x)dx + \int_{x^*}^{\lambda_4^N} \xi_{l_2,+}^N(x)dx.$$

From the jump discontinuities of $\xi_j^N(x)$ on $\mathcal{C}$, we obtain

$$\theta_{l_2}^N(\lambda_4^N) = \int_{\lambda_3^N}^{\lambda_4^N} \xi_{l_1,-}^N(x)dx + \oint_{\mathcal{S}} \xi_{l_2}^N(x)dx.$$

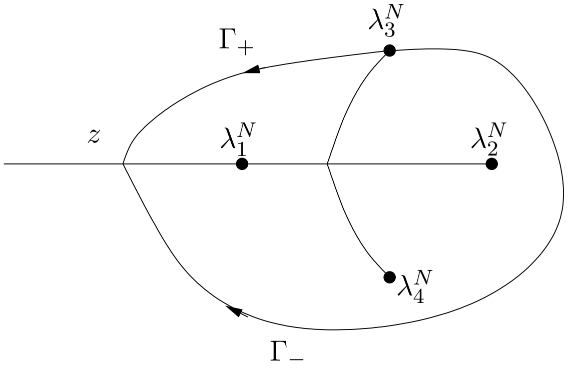

Figure 4: The contours Γ_+ and Γ_-.

Since branch cuts of $\xi_{l_2}^N$ are inside the loop $\mathcal{S}$, this loop can be deformed into a loop around $z=\infty$. By computing the integral using residue theorem, we obtain

$$\begin{aligned}\theta_2^N(\lambda_4^N)-\theta_3^N(\lambda_4^N)&=-2\pi i c_N(1-\beta_N),\quad a<1,\\ \theta_2^N(\lambda_4^N)-\theta_3^N(\lambda_4^N)&=2\pi i c_N\beta_N,\quad a>1.\end{aligned}$$

This, together with (3.49) gives the third and fourth equations in (3.47).

Let us now show that

$$\tilde{\theta}_{2,+}^N(z)=\tilde{\theta}_{2,-}^N(z)+2c_N(1-\beta_N)\pi i,\quad z\in(-\infty,\lambda_1^N]. \tag{3.51}$$

The corresponding equation for $\tilde{\theta}_1^N(z)$ and $\tilde{\theta}_3^N(z)$ can be proven in a similar way. Let $z\in(-\infty,\lambda_1^N]$ and let $\Gamma_\pm$ be contours from λ_3^N to z indicated as in Figure 4. Then we have

$$\theta_{2,\pm}^N(z)=\int_{\Gamma_\pm}\xi_2^N(x)dx.$$

Let Γ be the close loop on $\mathbb{C}$ such that $\Gamma=\Gamma_+-\Gamma_-$, then we have

$$\theta_{2,+}^N(z)=\theta_{2,-}^N(z)+\oint_\Gamma\xi_2^N(x)dx,\quad z\in(-\infty,\lambda_1^N].$$

By Cauchy's theorem, we can deform the loop Γ such that Γ becomes a loop around $z=\infty$. By computing the residue, we obtain

$$\theta_{2,+}^N(z)=\theta_{2,-}^N(z)+2c_N(1-\beta_N)\pi i,\quad z\in(-\infty,\lambda_1^N]. \tag{3.52}$$

Since $\tilde{\theta}_2^N(z)$ is a constant shift of $\theta_2^N(z)$, (3.52) implies (3.51).

By using similar argument, we can obtain the rest of the jump discontinuities. $\square$

We will conclude this section with the following results on the relative sizes of the $\mathrm{Re}\left(\tilde{\theta}_j^N(z)\right)$, which are essential in the implementation of the Riemann-Hilbert method.

Lemma 12. *The real parts of* $\tilde{\theta}_j^N(z)$ *in (3.42) are continuous in* $\mathbb{R}_+ \setminus [\lambda_1, \lambda_2]$ *and we have the followings.*

1. *Let* $x_L < x_R$ *be the points where* $\mathfrak{H}$ *intersects the real axis, then we have*

$$\begin{aligned} &\mathrm{Re}\left(\tilde{\theta}_1^N(z) - \tilde{\theta}_j^N(z)\right) > 0, \quad z \in \mathbb{R}_+ \setminus [x_L, x_R], \quad j = 1, 2, \\ &\mathrm{Re}\left(\tilde{\theta}_1^N(z) - \tilde{\theta}_{l_1}^N(z)\right) > 0, \quad z \in (0, \lambda_1^N), \\ &\mathrm{Re}\left(\tilde{\theta}_1^N(z) - \tilde{\theta}_{l_2}^N(z)\right) > 0, \quad z \in (\lambda_2^N, \infty). \end{aligned} \tag{3.53}$$

   where $l_1 = 2$, $l_2 = 3$ *for* $a > 1$ *and* $l_1 = 3$, $l_2 = 2$ *for* $a < 1$.

2. *Let* x^* *be the intersection point between* $\mathcal{C}$ *and* $\mathbb{R}$. *Then in a neighborhood* D_{x^*} *of* x^*, *we have*

$$\mathrm{Re}\left(\tilde{\theta}_1^N(z) - \tilde{\theta}_{l_1,-}^N(z)\right) < 0, \quad z \in D_{x^*} \cap \mathcal{C}. \tag{3.54}$$

   where the '+' and '−' subscripts denote the boundary values at the left and right hand sides of $\mathcal{C}$.

3. *On* $\mathcal{C}$, *we have*

$$\mathrm{Re}\left(\tilde{\theta}_{l_1,+}^N(z) - \tilde{\theta}_{l_1,-}^N(z)\right) < 0, \quad z \in \mathcal{C}. \tag{3.55}$$

   where the '+' and '−' subscripts denote the boundary values at the left and right hand sides of $\mathcal{C}$.

Proof. From (3.47), we see that the real parts of $\tilde{\theta}_j^N(z)$ are continuous in $\mathbb{R}_+ \setminus [\lambda_1^N, \lambda_2^N]$. Now from the proof of Proposition 3, we have, for $j = 2, 3$,

$$\begin{aligned} &\mathrm{Re}\left(\xi_1^N(z) - \xi_j^N(z)\right) > 0, \quad z \in (\lambda_2^N, \infty), \\ &\mathrm{Re}\left(\xi_1^N(z) - \xi_j^N(z)\right) < 0, \quad z \in (0, \lambda_1^N). \end{aligned} \tag{3.56}$$

From the definitions of $\theta_j^N(z)$ (3.29) and $\tilde{\theta}_j^N(z)$ (3.42), we obtain the second and the third equations in (3.53). To prove the first equation in (3.53), note that if $z \in (x_R, \infty)$, then z is in the region Ω_R in Figure 2. Similarly, if $z \in (0, x_L)$, then $z \in \Omega_L$. By considering the behavior of $\theta_2^N(z)$ and $\theta_3^N(z)$ at $z = \infty$, we see that

$$\begin{aligned} &\mathrm{Re}\left(\theta_{l_2}^N(z) - \theta_{l_1}^N(z)\right) > 0, \quad z \in (x_R, \infty), \\ &\mathrm{Re}\left(\theta_{l_1}^N(z) - \theta_{l_2}^N(z)\right) > 0, \quad z \in (0, x_L). \end{aligned} \tag{3.57}$$

From Proposition 2, we have $(x_L, x_R) \cap [\lambda_1^N, \lambda_2^N] \neq \emptyset$. This implies $x_L < x^* < \lambda_2^N$ and $x_R > x^* > \lambda_1^N$. Therefore, by the second, third equations in (3.53), Lemma 10, (3.57) and the fact that $\xi_1^N(z) - \xi_{l_j}^N(z)$ is purely imaginary on $\mathfrak{B}_j$, we obtain

$$\begin{aligned} &\mathrm{Re}\left(\tilde{\theta}_1^N(z) - \tilde{\theta}_{l_1}^N(z)\right) > \mathrm{Re}\left(\tilde{\theta}_1^N(z) - \tilde{\theta}_{l_2}^N(z)\right) \geq 0, \quad z \in (x_R, \infty), \\ &\mathrm{Re}\left(\tilde{\theta}_1^N(z) - \tilde{\theta}_{l_2}^N(z)\right) > \mathrm{Re}\left(\tilde{\theta}_1^N(z) - \tilde{\theta}_{l_1}^N(z)\right) \geq 0, \quad z \in (0, x_L). \end{aligned}$$

This, together with the second and the third equations in (3.53), give the first equation in (3.53).

We will now prove (3.54). Let us consider the left hand sides of (3.54) at the point x^*. Since $\xi_1^N(z) - \xi_{l_j}^N(z)$ is purely imaginary on $\mathfrak{B}_j$, we have

$$\int_{x^*}^{\lambda_j^N} \mathrm{Re}\left(\xi_1^N(x) - \xi_{l_j}^N(x)\right) dx = 0. \tag{3.58}$$

where the integration is performed along the real axis. Therefore we have

$$\mathrm{Re}\left(\tilde{\theta}_{l_1,+}^N(x^*)\right) = \mathrm{Re}\left(\tilde{\theta}_{l_2,-}^N(x^*)\right) = \mathrm{Re}\left(\tilde{\theta}_1^N(x^*)\right) \tag{3.59}$$

where the '+' and '−' subscripts indicate the boundary values on the left and right hand sides of $\mathcal{C}$. Now note that $\tilde{\theta}_{l_1,+}^N(x^*)$ is evaluated in the region Ω_1 of Figure 2 and $\tilde{\theta}_{l_2,-}^N(x^*)$ is evaluated in the region Ω_2. Again, by considering the behavior of $\tilde{\theta}_2^N(z)$ and $\tilde{\theta}_3^N(z)$ at $z = \infty$ and using the fact that $\mathrm{Re}\left(\tilde{\theta}_2^N - \tilde{\theta}_3^N\right)$ can only change signs across the sets $\mathfrak{H}$ and $\mathcal{C}$, we obtain

$$\pm\mathrm{Re}\left(\tilde{\theta}_{l_2,\pm}^N(x^*) - \tilde{\theta}_{l_1,\pm}^N(x^*)\right) > 0. \tag{3.60}$$

Then from (3.59) and (3.60), we obtain (3.54) at $z = x^*$. The statement for $z \in D_{x^*} \cap \mathcal{C}$ now follows from the continuities of the functions in (3.54) along $\mathcal{C}$.

Finally, note that inside the set Ω_2 between $\mathcal{C}$ and Ξ_R, (See Figure 2) we have the following inequalities.

$$\mathrm{Re}\left(\tilde{\theta}_{l_1}^N(z) - \tilde{\theta}_{l_2}^N(z)\right) > 0, \quad z \in \Omega_2, \tag{3.61}$$

by considering $z \in \Omega_2$ on the right hand side of $\mathcal{C}$ in (3.61) and making use of the jump conditions between $\tilde{\theta}_2^N$ and $\tilde{\theta}_3^N$ in (3.47), we obtain (3.55). $\square$

The final result in this section deals with the behavior of these real parts in a neighborhood of the interval $[\lambda_1^N, \lambda_2^N]$.

Lemma 13. *The open intervals (λ_1^N, x^*) and (x^*, λ_2^N) each has a neighborhood U_1 and U_2 in the complex plane such that*

$$\mathrm{Re}\left(\tilde{\theta}_j^N(z) - \tilde{\theta}_1^N(z)\right) > 0, \quad z \in U_{k_j}, \quad j = 2, 3. \tag{3.62}$$

where $k_2 = 1$, $k_3 = 2$ for $a > 1$ and $k_2 = 2$, $k_3 = 1$ for $a < 1$ and $\tilde{\theta}_j^N(z)$ are defined in (3.42).

Proof. Since $\xi_1^N(z) - \xi_j^N(z)$ is purely imaginary in $\mathfrak{B}_{k_j}$, we have

$$\int_{\lambda_{k_j}^N}^{z} \mathrm{Re}\left(\xi_1^N(x) - \xi_j(x)\right) dx = 0, \quad z \in \mathfrak{B}_{k_j}, \quad j = 1, 2, \tag{3.63}$$

where $\mathfrak{B}_{k_j}$ is defined in (3.41).

Let $\mathfrak{B}_{k_j}^0 = \mathfrak{B}_{k_j} \setminus \{\lambda_{k_j}^N\}$. Then on the positive and negative sides of $\mathfrak{B}_{k_j}^0$, the derivatives of the functions $\tilde{\theta}_{1,\pm}^N(z) - \tilde{\theta}_{j,\pm}^N(z)$ are given by $\xi_{1,\pm}^N(z) - \xi_{j,\pm}^N(z)$ and are purely imaginary. In fact, since $\xi_{1,+}(z) = m_{\hat{F}_N}$, we see that $\xi_{1,+}^N(z) - \xi_{j,+}^N(z) = 2\pi i \rho_N(z)$ where $\rho_N(z) > 0$ is the density function of $\hat{F}_N$. On the other hand, by the jump discontinuities (3.40), we see that $\xi_{1,-}^N(z) - \xi_{j,-}^N(z) = -2\pi i \rho_N(z)$. Hence by the Cauchy Riemann equation, the real part of $\tilde{\theta}_1^N(z) - \tilde{\theta}_j^N(z)$ is decreasing as we move from $\mathfrak{B}_{k_j}^0$ into the upper half plane. From (3.63) and (3.42), we see that $\mathrm{Re}\left(\tilde{\theta}_1^N(z) - \tilde{\theta}_j^N(z)\right) < 0$ for z in the upper half plane near $\mathfrak{B}_{k_j}^0$. Similarly, we also have $\mathrm{Re}\left(\tilde{\theta}_1^N(z) - \tilde{\theta}_j^N(z)\right) < 0$ for z in the lower half plane near $\mathfrak{B}_{k_j}^0$. This implies (3.62) is true in a neighborhood U_{k_j} of $\mathfrak{B}_{k_j}^0$. □

4 Riemann-Hilbert analysis

We can now implement the Riemann-Hilbert method to obtain the strong asymptotics for the multiple Laguerre polynomials introduced in Section 2 and use it to prove Theorem 3. The analysis is very similar to those in [12] (See also [26]).

Let $C(f)$ be the Cauchy transform of the function $f(z) \in L^2(\mathbb{R}_+)$ in $\mathbb{R}_+$

$$C(f)(z) = \frac{1}{2\pi i} \int_{\mathbb{R}_+} \frac{f(s)}{s - z} ds, \tag{4.1}$$

and let $w_1(z)$ and $w_2(z)$ be the weights of the multiple Laguerre polynomials.

$$w_1(z) = z^{M-N} e^{-Mz}, \quad w_2(z) = z^{M-N} e^{-Ma^{-1}z}, \tag{4.2}$$

Denote by κ_1 and κ_2 the constants

$$\kappa_1 = -2\pi i \left(h_{N_0-1,N_1}^{(1)}\right)^{-1}, \quad \kappa_2 = -2\pi i \left(h_{N_0,N_1-1}^{(2)}\right)^{-1}.$$

Then due to the orthogonality condition (2.1), the following matrix

$$Y(z) = \begin{pmatrix} P_{N_0,N_1}(z) & C(P_{N_0,N_1} w_1)(z) & C(P_{N_0,N_1} w_2)(z) \\ \kappa_1 P_{N_0-1,N_1}(z) & \kappa_1 C(P_{N_0-1,N_1} w_1)(z) & \kappa_1 C(P_{N_0-1,N_1} w_2)(z) \\ \kappa_2 P_{N_0,N_1-1}(z) & \kappa_2 C(P_{N_0,N_1-1} w_1)(z) & \kappa_2 C(P_{N_0,N_1-1} w_2)(z) \end{pmatrix} \tag{4.3}$$

is the unique solution of the following Riemann-Hilbert problem.

$$\begin{aligned}
&1. \quad Y(z) \text{ is analytic in } \mathbb{C} \setminus \mathbb{R}_+, \\
&2. \quad Y_+(z) = Y_-(z) \begin{pmatrix} 1 & w_1(z) & w_2(z) \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{pmatrix}, \quad z \in \mathbb{R}_+ \\
&3. \quad Y(z) = \left(I + O(z^{-1})\right) \begin{pmatrix} z^N & 0 & 0 \\ 0 & z^{-N_0} & 0 \\ 0 & 0 & z^{-N_1} \end{pmatrix}, \quad z \to \infty, \\
&4. \quad Y(z) = O(1), \quad z \to 0.
\end{aligned} \tag{4.4}$$

By a similar computation as the one in [10] and [14], we can express the kernel (2.5) in terms of the solution of the Riemann-Hilbert problem $Y(z)$.

$$\begin{aligned}
K_{M,N}(x,y) &= \frac{(xy)^{\frac{M-N}{2}} \left(e^{-My} \left[Y_+^{-1}(y)Y_+(x)\right]_{21} + e^{-Ma^{-1}y} \left[Y_+^{-1}(y)Y_+(x)\right]_{31}\right)}{2\pi i(x-y)}, \\
&= \frac{(xy)^{\frac{M-N}{2}}}{2\pi i(x-y)} \begin{pmatrix} 0 & e^{-My} & e^{-Ma^{-1}y} \end{pmatrix} Y_+^{-1}(y)Y_+(x) \begin{pmatrix} 1 \\ 0 \\ 0 \end{pmatrix}
\end{aligned} \tag{4.5}$$

where A_{21} and A_{31} are the 21^{th} and 31^{th} entries of A.

4.1 First transformation of the Riemann-Hilbert problem

We should now use the functions $\tilde{\theta}_j^N(z)$ in (3.42) to deform the Riemann-Hilbert problem (4.4). Our goal is to deform the Riemann-Hilbert problem so that it can be approximated by a Riemann-Hilbert problem that is explicitly solvable. As in [12] and [26], the set $\mathfrak{H}$ in (3.31) will be important to the construction.

We will now start deforming the Riemann-Hilbert problem (4.4). First let us define the functions $g_j^N(z)$ to be

$$\begin{aligned}
&g_1^N(z) = \tilde{\theta}_1^N(z) + (1-c_N)\log z, \quad g_2^N(z) = \tilde{\theta}_2^N(z) + z, \\
&g_3^N(z) = \tilde{\theta}_3^N(z) + \frac{z}{a}.
\end{aligned} \tag{4.6}$$

where $\tilde{\theta}_j^N(z)$ is defined in (3.42) and the branch cut of $\log z$ in $g_1^N(z)$ is chosen to be the negative real axis.

We then define $T(z)$ to be

$$T(z) = diag\left(e^{-Ml_1^N}, e^{-M\tilde{l}_2^N}, e^{-M\tilde{l}_3^N}\right) Y(z) diag\left(e^{Mg_1^N(z)}, e^{Mg_2^N(z)}, e^{Mg_3^N(z)}\right), \tag{4.7}$$

where $\tilde{l}_2^N$ and $\tilde{l}_3^N$ are given by

$$\tilde{l}_2^N = \begin{cases} l_2^N - \theta_{2,+}^N(\lambda_1^N) + \theta_{1,-}^N(\lambda_1^N), & a > 1; \\ l_2^N - \theta_{2,+}^N(\lambda_2^N), & a < 1. \end{cases}$$

$$\tilde{l}_3^N = \begin{cases} l_3^N(z) - \theta_{3,+}^N(\lambda_2^N), & a > 1; \\ l_3^N(z) - \theta_{3,+}^N(\lambda_1^N) + \theta_{1,-}^N(\lambda_1^N), & a < 1. \end{cases}$$

The matrix $T(z)$ will satisfy the following Riemann-Hilbert problem.

$$\begin{aligned} &1. \quad T(z) \text{ is analytic in } \mathbb{C} \setminus (\mathbb{R} \cup \mathcal{C}), \\ &2. \quad T_+(z) = T_-(z) J_T(z), \quad z \in \mathbb{R} \cup \mathcal{C}, \\ &3. \quad T(z) = I + O(z^{-1}), \quad z \to \infty, \\ &4. \quad T(z) = O(1), \quad z \to 0. \end{aligned} \tag{4.8}$$

where $J_T(z)$ is the following matrix

$$J_T(z) = \begin{pmatrix} e^{M\left(\tilde{\theta}_{1,+}^N(z) - \tilde{\theta}_{1,-}^N(z)\right)} & e^{M\left(\tilde{\theta}_{2,+}^N(z) - \tilde{\theta}_{1,-}^N(z)\right)} & e^{M\left(\tilde{\theta}_{3,+}^N(z) - \tilde{\theta}_{1,-}^N(z)\right)} \\ 0 & e^{M\left(\tilde{\theta}_{2,+}^N(z) - \tilde{\theta}_{2,-}^N(z)\right)} & 0 \\ 0 & 0 & e^{M\left(\tilde{\theta}_{3,+}^N(z) - \tilde{\theta}_{3,-}^N(z)\right)} \end{pmatrix}, \tag{4.9}$$

By applying Lemma 11 to the $\tilde{\theta}_j^N(z)$, we can simplify the jump matrix $J_T(z)$. In particular, on $\mathfrak{B}_{k_2}$ in (3.41), we have

$$J_T(z) = \begin{pmatrix} e^{M\left(\tilde{\theta}_1^N(z) - \tilde{\theta}_2^N(z)\right)_+} & 1 & e^{M\left(\tilde{\theta}_{3,+}^N(z) - \tilde{\theta}_{1,-}^N(z)\right)} \\ 0 & e^{M\left(\tilde{\theta}_1^N(z) - \tilde{\theta}_2^N(z)\right)_-} & 0 \\ 0 & 0 & 1 \end{pmatrix}, \tag{4.10}$$

while on $\mathfrak{B}_{k_3}$, we have

$$J_T(z) = \begin{pmatrix} e^{M\left(\tilde{\theta}_1^N(z) - \tilde{\theta}_3^N(z)\right)_+} & e^{M\left(\tilde{\theta}_{2,+}^N(z) - \tilde{\theta}_{1,-}^N(z)\right)} & 1 \\ 0 & 1 & 0 \\ 0 & 0 & e^{M\left(\tilde{\theta}_1^N(z) - \tilde{\theta}_3^N(z)\right)_-} \end{pmatrix}, \tag{4.11}$$

On the rest of the positive real axis, the jump matrix becomes

$$J_T(z) = \begin{pmatrix} 1 & e^{M\left(\tilde{\theta}_{2,+}^N(z) - \tilde{\theta}_{1,-}^N(z)\right)} & e^{M\left(\tilde{\theta}_{3,+}^N(z) - \tilde{\theta}_{1,-}^N(z)\right)} \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{pmatrix}. \tag{4.12}$$

This is because $Mc_N\beta_N = N_1$, $Mc_N(1-\beta_N) = N_0$ and $Mc_N = N$ are all integers. And on the negative real axis, the matrix $T(z)$ has no jump for the same reason. Note that the

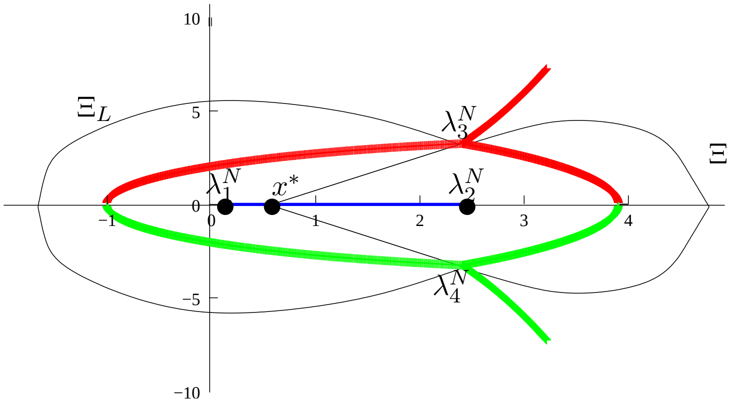

Figure 5: The contours Ξ_L and Ξ_R.

jump matrix $J_T(z)$ is continuous at $z = 0$ as the off-diagonal entries of (4.12) contain the factor $e^{-M\theta_{1,-}^N(z)}$ which vanishes at the origin.

The jump matrix on $\mathcal{C}$ is given by

$$J_T(z) = \begin{pmatrix} 1 & 0 & 0 \\ 0 & e^{M\left(\tilde{\theta}_{2,+}^N(z)-\tilde{\theta}_{2,-}^N(z)\right)} & 0 \\ 0 & 0 & e^{M\left(\tilde{\theta}_{3,+}^N(z)-\tilde{\theta}_{3,-}^N(z)\right)} \end{pmatrix}. \tag{4.13}$$

The Riemann-Hilbert problem for $T(z)$ now takes same form as the one in [12] (See also [26]) and the techniques developed there can now be applied to our problem.

4.2 Lens opening and approximation of the Riemann-Hilbert problem

We will now apply the global lens opening technique developed in [12]. We will have to use the properties of the set $\mathfrak{H}$ in (3.31) to define the global lens contour.

By Proposition 2, the set union of the set $\mathfrak{H}$ and $\mathcal{C}$ divides the complex plane into 4 regions Ω_L, Ω_R, Ω_1 and Ω_2. The region Ω_L (Ω_R) is an open region that lies on the left (right) hand side of the contours $\mathfrak{H}_{\pm}^{\infty}$ and $\mathfrak{H}_L$. ($\mathfrak{H}_R$) The region Ω_1 (Ω_2) is the region bounded by $\mathfrak{H}_L$ ($\mathfrak{H}_R$) and $\mathcal{C}$. (See Figure 2)

By considering the behavior of $\theta_2^N(z) - \theta_3^N(z)$ near $z = \infty$ in (3.30), we see that for $a < 1$ ($a > 1$), $\mathrm{Re}\left(\theta_2^N(z) - \theta_3^N(z)\right)$ is negative (positive) in Ω_L and positive (negative) in Ω_R. Let us define the contour Ξ_L (Ξ_R) to be a contour from λ_4^N to λ_3^N in Ω_L (Ω_R) such that Ξ_L intersects $\mathbb{R}$ at a point $x_1 < 0$ and Ξ_R intersects $\mathbb{R}$ at a point $x_2 > \lambda_2^N$. (See Figure 5)

Let us define the lens contours $\Xi_{\pm}^j$, $j = 1, 2$ around the branch cut $[\lambda_1^N, \lambda_2^N]$ as follows. The contours $\Xi_{\pm}^j$ are contours in the neighborhoods U_j in Lemma 13 joining λ_j^N and $\mathcal{C}$ in the upper/lower half plane. Together with the contours Ξ_L and Ξ_R, the lens contours are depicted in Figure 6. Let the matrices $\mathcal{G}_1$, $\mathcal{G}_2$, $\mathcal{G}_3$, $\mathcal{G}_4$ be the followings

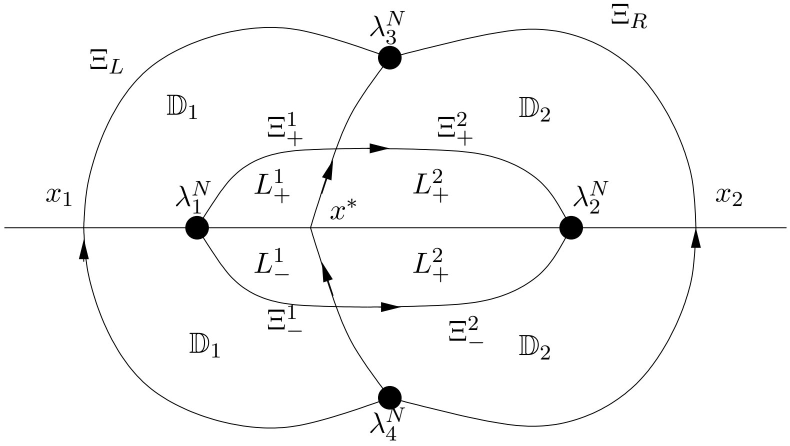

Figure 6: The lens contours.

$$\begin{aligned}
\mathcal{G}_1 &= \begin{pmatrix} 1 & 0 & 0 \\ 0 & 1 & -e^{M\left(\tilde{\theta}_3^N(z)-\tilde{\theta}_2^N(z)\right)} \\ 0 & 0 & 1 \end{pmatrix}, \quad \mathcal{G}_2 = \begin{pmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & -e^{M\left(\tilde{\theta}_2^N(z)-\tilde{\theta}_3^N(z)\right)} & 1 \end{pmatrix}, \\
\mathcal{G}_3 &= \begin{pmatrix} 1 & 0 & 0 \\ -e^{M\left(\tilde{\theta}_1^N(z)-\tilde{\theta}_2^N(z)\right)} & 1 & 0 \\ 0 & 0 & 1 \end{pmatrix}, \quad \mathcal{G}_4 = \begin{pmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ -e^{M\left(\tilde{\theta}_1^N(z)-\tilde{\theta}_3^N(z)\right)} & 0 & 1 \end{pmatrix}.
\end{aligned} \tag{4.14}$$

We will now define the matrix $S(z)$ to be $S(z) = T(z)$ outside of the lens region. Inside the lens region, we define $S(z)$ to be

$$\begin{aligned}
&\text{For } a < 1, \quad S(z) = T(z)\mathcal{G}_2, \quad z \in \mathbb{D}_1, \quad S(z) = T(z)\mathcal{G}_1, \quad z \in \mathbb{D}_2, \\
&\qquad\qquad S(z) = T(z)\mathcal{G}_2\mathcal{G}_4^{\pm 1}, \quad z \in L_\pm^1, \quad S(z) = T(z)\mathcal{G}_1\mathcal{G}_3^{\pm 1}, \quad z \in L_\pm^2. \\
&\text{For } a > 1, \quad S(z) = T(z)\mathcal{G}_1, \quad z \in \mathbb{D}_1, \quad S(z) = T(z)\mathcal{G}_2, \quad z \in \mathbb{D}_2, \\
&\qquad\qquad S(z) = T(z)\mathcal{G}_1\mathcal{G}_3^{\pm 1}, \quad z \in L_\pm^1, \quad S(z) = T(z)\mathcal{G}_2\mathcal{G}_4^{\pm 1}, \quad z \in L_\pm^2.
\end{aligned} \tag{4.15}$$

Let Ξ be the union of the lens contours.

$$\Xi = \Xi_L \cup \Xi_R \cup \left(\cup_{j=1}^2 \Xi_j^+ \cup \Xi_j^-\right).$$

Then by using Lemma 11, it is easy to check that $S(z)$ satisfies the following Riemann-Hilbert problem.

$$\begin{aligned}
&1. \quad S(z) \text{ is analytic in } \mathbb{C} \setminus (\mathbb{R}_+ \cup \Xi \cup \mathcal{C}), \\
&2. \quad S_+(z) = S_-(z) J_S(z), \quad z \in (\mathbb{R}_+ \cup \Xi \cup \mathcal{C}), \\
&3. \quad S(z) = I + O(z^{-1}), \quad z \to \infty, \\
&4. \quad S(z) = O(1), \quad z \to 0.
\end{aligned} \tag{4.16}$$

where the matrix $J_S(z)$ is given by the following. Let $\mathcal{C} = \cup_{j=0}^2 \mathcal{C}_j$ where $\mathcal{C}_0$ is the boundary between $\mathbb{D}_1$ and $\mathbb{D}_2$, $\mathcal{C}_1$ is the boundary between L_-^1 and L_-^2 and $\mathcal{C}_2$ is the boundary between

L_+^1 and L_+^2. Then on $\mathcal{C}$, the jump matrix $J_S(z)$ is given by

$$
\begin{aligned}
&\text{For } a<1, \quad J_S(z)=\begin{pmatrix}1 & 0 & 0\\ 0 & 0 & 1\\ 0 & -1 & e^{M\left(\tilde\theta^N_{3,+}(z)-\tilde\theta^N_{3,-}(z)\right)}\end{pmatrix}, \quad z\in\mathcal{C}_0,\\
&\qquad\qquad\quad J_S(z)=\begin{pmatrix}1 & 0 & 0\\ 0 & 0 & 1\\ (-1)^{l-1}e^{M\left(\tilde\theta^N_1(z)-\tilde\theta^N_{3,-}(z)\right)} & -1 & e^{M\left(\tilde\theta^N_{3,+}(z)-\tilde\theta^N_{3,-}(z)\right)}\end{pmatrix},\\
&\qquad\qquad\qquad z\in\mathcal{C}_l, \quad l=1,2.\\
&\text{For } a>1, \quad J_S(z)=\begin{pmatrix}1 & 0 & 0\\ 0 & e^{M\left(\tilde\theta^N_{2,+}(z)-\tilde\theta^N_{2,-}(z)\right)} & -1\\ 0 & 1 & 0\end{pmatrix}, \quad z\in\mathcal{C}_0,\\
&\qquad\qquad\quad J_S(z)=\begin{pmatrix}1 & 0 & 0\\ (-1)^{l-1}e^{M\left(\tilde\theta^N_1(z)-\tilde\theta^N_{2,-}(z)\right)} & e^{M\left(\tilde\theta^N_{2,+}(z)-\tilde\theta^N_{2,-}(z)\right)} & -1\\ 0 & 1 & 0\end{pmatrix},\\
&\qquad\qquad\qquad z\in\mathcal{C}_l, \quad l=1,2.
\end{aligned}
\tag{4.17}
$$

On the lens contour Ξ, the jump $J_S(z)$ is given by

$$
\begin{aligned}
&\text{For } a<1, \quad J_S(z)=\mathcal{G}_2^{-1}, \quad z\in\Xi_L, \quad J_S(z)=\mathcal{G}_1, \quad z\in\Xi_R,\\
&\qquad\qquad\quad J_S(z)=\mathcal{G}_4^{-1}, \quad z\in\Xi_1^{\pm}, \quad J_S(z)=\mathcal{G}_3^{-1}, \quad z\in\Xi_2^{\pm},\\
&\text{For } a>1, \quad J_S(z)=\mathcal{G}_1^{-1}, \quad z\in\Xi_L, \quad J_S(z)=\mathcal{G}_2, \quad z\in\Xi_R,\\
&\qquad\qquad\quad J_S(z)=\mathcal{G}_3^{-1}, \quad z\in\Xi_1^{\pm}, \quad J_S(z)=\mathcal{G}_4^{-1}, \quad z\in\Xi_2^{\pm}.
\end{aligned}
\tag{4.18}
$$

Finally, let $\mathbb{R}_j$ be the following.

$$
\mathbb{R}_1=(0,\lambda_1^N), \quad \mathbb{R}_2=(\lambda_2^N,x_2). \tag{4.19}
$$

Then on the real axis, the jumps of $S(z)$ are given by

$$
\begin{aligned}
&J_S(z)=\begin{pmatrix}1 & e^{M\left(\tilde\theta^N_{2,+}(z)-\tilde\theta^N_{1,-}(z)\right)} & 0\\ 0 & 1 & 0\\ 0 & 0 & 1\end{pmatrix}, \quad z\in\mathbb{R}_{k_2},\\
&J_S(z)=\begin{pmatrix}1 & 0 & e^{M\left(\tilde\theta^N_{3,+}(z)-\tilde\theta^N_{1,-}(z)\right)}\\ 0 & 1 & 0\\ 0 & 0 & 1\end{pmatrix}, \quad z\in\mathbb{R}_{k_3},\\
&J_S(z)=\begin{pmatrix}0 & 1 & 0\\ -1 & 0 & 0\\ 0 & 0 & 1\end{pmatrix}, \quad z\in\mathfrak{B}_{k_2}, \quad J_S(z)=\begin{pmatrix}0 & 0 & 1\\ 0 & 1 & 0\\ -1 & 0 & 0\end{pmatrix}, \quad z\in\mathfrak{B}_{k_3}.
\end{aligned}
\tag{4.20}
$$

where $k_2=1$, $k_3=2$ for $a>1$ and $k_2=2$, $k_3=1$ for $a<1$. On the rest of the positive real axis, the jump is given by (4.12).

By considering the behavior of $\theta_2^N(z)-\theta_3^N(z)$ near $z=\infty$ in (3.30) and by making use of Lemma 10, we see that for $a<1$ ($a>1$), $\mathrm{Re}\left(\tilde{\theta}_2^N(z)-\tilde{\theta}_3^N(z)\right)$ is negative (positive) in Ξ_L and positive (negative) in Ξ_R. Hence, from (4.18), we see that the off-diagonal entries in $J_S(z)$ become exponentially small on Ξ_L and Ξ_R as $M\to\infty$ outside of some small neighborhoods D_k around the points λ_k^N. By Lemma 13, we see that, away from the points λ_k^N, the jump matrices on the lens contours $\Xi_1^{\pm}$ and $\Xi_2^{\pm}$ are all exponentially close to the identity matrix as $M\to\infty$. By (3.53) and the fact that $x_2>x_R$, it follows that $J_S(z)$ are also exponentially close to the identity matrix on $\mathbb{R}_+\setminus\left([\lambda_1^N,\lambda_2^N]\cup D_1\cup D_2\right)$ as $M\to\infty$. Now by (3.54), we see that the for $a<1$, the 31^{th} entry of $J_S(z)$ in $\mathcal{C}_1\cup\mathcal{C}_2$ (4.17) is exponentially small in M, while for $a>1$, the 21^{th} entry of $J_S(z)$ in $\mathcal{C}_1\cup\mathcal{C}_2$ is exponentially small in M. Finally, by (3.55), we see that for $a<1$, the 33^{th} entry of $J_S(z)$ in $\mathcal{C}$ is also exponentially small in M, while for $a>1$, the 22^{th} entry of $J_S(z)$ in $\mathcal{C}$ is exponentially small in M. This suggests the following approximation to the Riemann-Hilbert problem (4.16).

$$\begin{aligned}
&1.\quad S^{\infty}(z) \text{ is analytic in } \mathbb{C}\setminus\left([\lambda_1^N,\lambda_2^N]\cup\mathcal{C}\right),\\
&2.\quad S^{\infty}_{+}(z)=S^{\infty}_{-}(z)J_{\infty}(z),\quad z\in[\lambda_1^N,\lambda_2^N]\cup\mathcal{C},\\
&3.\quad S^{\infty}(z)=I+O(z^{-1}),\quad z\to\infty,\\
&4.\quad S^{\infty}(z)=O\left((z-\lambda_j^N)^{-\frac{1}{4}}\right),\quad z\to\lambda_j^N,\quad j=1,\ldots,4.
\end{aligned}\tag{4.21}$$

where the matrix $J_\infty(z)$ is the same as $J_S(z)$ on $[\lambda_1^N,\lambda_2^N]$ and on $\mathcal{C}$, it is given by

$$\begin{aligned}
&\text{For } a<1,\quad J_{\infty}(z)=\begin{pmatrix}1&0&0\\0&0&1\\0&-1&0\end{pmatrix},\quad z\in\mathcal{C},\\
&\text{For } a>1,\quad J_{\infty}(z)=\begin{pmatrix}1&0&0\\0&0&-1\\0&1&0\end{pmatrix},\quad z\in\mathcal{C}.
\end{aligned}\tag{4.22}$$

In the next section we will give an explicit solution to this Riemann-Hilbert problem and we will eventually show that $S^{\infty}(z)$ is a good approximation of $S(z)$ when z is outside of the small neighborhood D_k of the branch point λ_k^N.

4.3 Outer parametrix

Let $\mathcal{L}_N$ be the Riemann surface defined by (3.27) and let Γ_j be the images of $\mathfrak{B}_j$ on $\mathcal{L}_N$ under the map $\xi_{1,+}^N(z)$. That is

$$\Gamma_j=\left\{(z,\xi)\in\mathcal{L}_N|\quad \xi=\xi_{1,+}^N(z),\quad z\in\mathfrak{B}_j.\right\},\quad j=1,2.\tag{4.23}$$

Similarly, we define Γ_c to be the image of $\mathcal{C}$.

$$\Gamma_c=\left\{(z,\xi)\in\mathcal{L}_N|\quad \xi=\xi_{l_2,+}^N(z),\quad z\in\mathcal{C}.\right\},\tag{4.24}$$

where $l_1 = 2$, $l_2 = 3$ when $a > 1$ and $l_1 = 3$, $l_2 = 2$ when $a < 1$.

Let us now define the functions $S_k^\infty(\xi)$, $k = 1, 2, 3$ to be the following functions on $\mathcal{L}_N$.

$$\begin{aligned}
S_1^\infty(\xi) &= a\sqrt{\prod_{j=1}^4 \gamma_j^N}\frac{(\xi+1)(\xi+a^{-1})}{\sqrt{\prod_{j=1}^4(\xi-\gamma_j^N)}},\\
S_2^\infty(\xi) &= \frac{a\sqrt{\prod_{j=1}^4(1+\gamma_j^N)}}{a-1}\frac{\xi(\xi+a^{-1})}{\sqrt{\prod_{j=1}^4(\xi-\gamma_j^N)}},\\
S_3^\infty(\xi) &= \frac{\sqrt{\prod_{j=1}^4(1+a\gamma_j^N)}}{1-a}\frac{\xi(\xi+1)}{\sqrt{\prod_{j=1}^4(\xi-\gamma_j^N)}}.
\end{aligned} \tag{4.25}$$

where γ_k^N are the roots of polynomial (3.28). The branch cuts of the square root in (4.25) are chosen to be the contours Γ_1, Γ_2 (4.23) and Γ_c (4.24) in $\mathcal{L}^N$.

By using the asymptotic behavior of the functions $\xi_m^N(z)$ (1.17) and (3.13), with c and β replaced by c_N and β_N, we see that the all the functions $S_k^\infty(\xi)$ are holomorphic near $\xi_m^N(0)$ for $m = 1, 2, 3$. Moreover, at the points $\xi_m^N(\infty)$, these functions satisfy

$$S_k^\infty(\xi_m^N(\infty)) = \delta_{mk}, \quad k, m = 1, 2, 3. \tag{4.26}$$

Let us define $S^\infty(z)$ to be the following matrix on $z \in \mathbb{C}$.

$$\left(S^\infty(z)\right)_{im} = S_i^\infty(\xi_m^N(z)), \quad 1 \le i, m \le 3. \tag{4.27}$$

Then, since the branch cut of the square root in (4.25) are chosen to be Γ_j and Γ_c, we have, from the jump discontinuities of the $\xi_m^N(z)$ (3.40), the following

$$\begin{aligned}
S_i^\infty(\xi_{1,\pm}^N(z)) &= \mp S_i^\infty(\xi_{l,\mp}^N(z)), \quad z \in \mathfrak{B}_{k_l}, \quad i = 1, 2, 3, \quad l = 2, 3,\\
S_i^\infty(\xi_{l_2,\pm}^N(z)) &= \mp S_i^\infty(\xi_{l_1,\mp}^N(z)), \quad z \in \mathcal{C}, \quad i = 1, 2, 3.
\end{aligned} \tag{4.28}$$

From this and the asymptotic behavior (4.26) of the $S_i^\infty(\xi)$ at $z = \infty$ and its behavior at the branch points λ_j^N, we see that the matrix $S^\infty(z)$ satisfies the Riemann-Hilbert problem (4.16).

Proposition 4. *The matrix $S^\infty(z)$ defined by (4.27) satisfies the Riemann-Hilbert problem (4.21).*

4.4 Local parametrices near the edge points λ_k^N

Near the edge points λ_k^N, the approximation of $S(z)$ by $S^\infty(z)$ failed and we must solve the Riemann-Hilbert problem exactly near these points and match the solutions to the outer parametrix (4.27) up to an error term of order $O(M^{-1})$. To be precise, let $\delta > 0$ and let

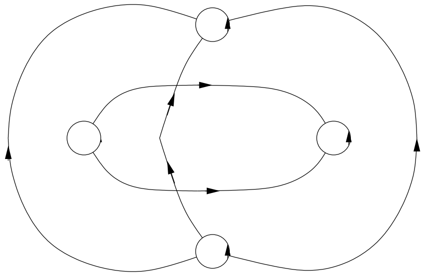

Figure 7: The contour Γ_R.

D_k be a disc of radius δ centered at the point λ_k^N, $k=1,\ldots,4$. We would like to construct local parametrices $S^k(z)$ in D_k such that

$$\begin{aligned} &1. \quad S^k(z) \text{ is analytic in } D_k \setminus (D_k \cap (\mathbb{R}\cup\Xi\cup\mathcal{C})),\\ &2. \quad S^k_+(z) = S^k_-(z) J_S(z), \quad z\in D_k\cap(\mathbb{R}\cup\Xi\cup\mathcal{C}),\\ &3. \quad S^k(z) = \left(I+O(M^{-1})\right) S^\infty(z), \quad z\in\partial D_k. \end{aligned} \tag{4.29}$$

The local parametrices $S^k(z)$ can be constructed by using the Airy function as in [12] (See also [26]). Since the construction is identical to that in [12] and [26], we shall not repeat the details here and refer the readers to these 2 papers.

4.5 Last transformation of the Riemann-Hilbert problem

Let us now show that the parametrices constructed in Section 4.3 and Section 4.4 are indeed good approximation to the solution $S(z)$ of the Riemann-Hilbert problem (4.16).

Let us define $R(z)$ to be the following matrix

$$R(z) = \left\{ \begin{array}{ll} S(z)\left(S^k(z)\right)^{-1}, & z \text{ inside } D_k,\ k=1,\ldots,4;\\ S(z)\left(S^\infty(z)\right)^{-1}, & z \text{ outside of } D_k,\ k=1,\ldots,4. \end{array}\right. \tag{4.30}$$

Then the function $R(z)$ has jump discontinuities on the contour Γ_R shown in Figure 7. In particular, $R(z)$ satisfies the Riemann-Hilbert problem

$$\begin{aligned} &1. \quad R(z) \text{ is analytic in } \mathbb{C}\setminus\Gamma_R\\ &2. \quad R_+(z) = R_-(z) J_R(z)\\ &3. \quad R(z) = I + O(z^{-1}), \quad z\to\infty,\\ &4. \quad R(z) = O(1), \quad z\to 0. \end{aligned} \tag{4.31}$$

From the definition of $R(z)$ (4.30), it is easy to see that the jumps $J_R(z)$ has the following order of magnitude.

$$J_R(z) = \left\{ \begin{array}{ll} I+O(M^{-1}), & z\in\partial D_k,\ k=1,\ldots,4\ ;\\ I+O\left(e^{-M\eta}\right), & \text{for some fixed } \eta>0 \text{ on the rest of } \Gamma_R. \end{array}\right. \tag{4.32}$$

Then by the standard theory, [17], [18], [19], we have

$$R(z) = I + O\left(\frac{1}{M(|z|+1)}\right), \tag{4.33}$$

uniformly in $\mathbb{C}$.

In particular, the solution $S(z)$ of the Riemann-Hilbert problem (4.16) can be approximated by $S^{\infty}(z)$ and $S^{k}(z)$ as

$$S(z) = \begin{cases} \left(I + O\left(M^{-1}\right)\right) S^{k}(z), & z \in D_k,\ k = 1, \ldots, 4; \\ \left(I + O\left(M^{-1}\right)\right) S^{\infty}(z), & z \text{ outside of } D_k,\ k = 1, \ldots, 4. \end{cases} \tag{4.34}$$

5 Universality of the correlation kernel

The the universality result Theorem 3 can now be proven by using the asymptotics of the multiple Laguerre polynomials obtained in the last section. The proof is the same as the ones in Section 9 of [11], [12] and [28] and we shall leave the readers to verify the details.

6 Conclusions

This paper complements the results obtained in our earlier paper [28] on the universality of complex Wishart ensembles 2 with distinct eigenvalues and the number of each eigenvalue becomes large as the size of the ensemble goes to infinity. By using results in the Stieltjes transform of the limiting eigenvalue distribution, we were able to overcome difficulties in determining the sheet structure of the Riemann surface (1.5). This, together with an analysis of the topology of the zero set of a function $h(x)$ (1.18), enables us to apply the Deift-Zhou steepest descent method to obtain asymptotic formula for the eigenvalue correlation function. Together with [28], we showed that unless the discriminant of the polynomial (1.6) is zero, the local eigenvalue statistics are given by the sine-kernel (1.12) in the bulk and the Airy kernel (1.13) in the edge of the spectrum. We have also shown that the largest eigenvalue is distributed according to the Tracy-Widom distribution (1.16).

When the discriminant Δ of (1.6) becomes zero, the ensemble goes through a phase transition in which the support of the limiting eigenvalue density changes from 1 interval to 2 intervals. This phase transition can be studied by the method developed in [13] and the eigenvalue correlation function will be given by the Pearcey kernel near the critical point of the spectrum, the point where the support is splitting.

The use of Stieltjes transform to provide a Riemann surface needed for the implementation of the Riemann-Hilbert analysis can be generalized to cases where the covariance matrix has more than 2 distinct eigenvalues. However, when the Riemann surface has more than 2 complex branch points, the determination of the zero set $\mathfrak{H}$ in (3.31) is very complicated and a full generalization to these cases is still a very challenging open problem.
